SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2003 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes *JH* and *HR*. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ukans.edu/~ssar/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Theodora Pinou, SSAR Treasurer, Department of Ecology & Evolutionary Biology, Osborn Memorial Labs, Yale University, 165 Prospect Street, New Haven, Connecticut 06520-8106, USA. Fax: (203) 432-5176; e-mail: theodora.pinou@yale.edu

Future Annual Meetings

2003 — Hotel Tropical, Manaus, Brazil, 26 June–2 July (with ASIH, HL)
2004 — University of Oklahoma, Norman, Oklahoma (with ASIH, HL)
2005 — University of South Florida, Tampa, Florida (with ASIH, HL)

Society for the Study of Amphibians and Reptiles
2003 Annual Meeting

together with

The Herpetologists' League

and

American Society of Ichthyologists and Herpetologists

26 June – 1 July 2003
Tropical Hotel Conference Center
(on the Rio Negro)
Manaus, Amazonas, Brazil

Richard C. Vogt and Ning Labbish Chao, Local Chairs

Keynote Address: "In Search of El Dorado: The Neotropical Herpetofauna," by William E. Duellman (University of Kansas), The Herpetologists' League Distinguished Herpetologist for 2003.

SSAR President's Travelogue: "From the Amazonian Floating Meadows to the Surumoni Canopy Crane Project: Frog Research in Amazonia," by Walter Hödl (University of Vienna).

Symposium: "Reproductive Biology and Phylogeny of Urodela (Amphibia)." *Organizer:* David M. Sever, Saint Mary's College (dsever@jade.saintmarys.edu).

Symposium: "New Frontiers in Freshwater Turtle Ecology." *Organizers:* Richard C. Vogt, Instituto Nacional de Pesquisas da Amazônia–INPA (vogt@inpa.gov.br) and Paulo Andrade, IBAMA.

Symposium: "Amazonian Frogs: Taxonomic and Ecological Diversity." Organizers: Janalee P. Caldwell, University of Oklahoma (caldwell@ou.edu); William E. Duellman, University of Kansas; Albertina Lima, INPA.

Symposium: "Sequestered Defensive Compounds in Amphibians and Reptiles." *Organizer*: Alan H. Savitzky, Old Dominion University (asavitzk@odu.edu).

Symposium: "Disease Ecology and Global Amphibian Decline." *Organizers*: Mathew J. Parris, Memphis State University (mparris@memphis.edu); Andrew Storfer, Washington State University.

Symposium: "Amphibian Metamorphosis: 30 Years of Progress." *Organizer*: Christopher K. Beachy, Clarke College (cbeachy@keller.clarke.edu).

Symposium: "Exotics and Extinction: Fates of Fishes, Amphibians, and Reptiles in the Americas." *Organizers*: Harry Grier, University of Florida (harry.grier@fwc.state.fl.us) and Maria del Carmen Uribe Aranzabal.

Symposium: "The Biology of Hypogean Fishes, Amphibians, and Reptiles." Organizer: Aldemaro Romero, Macalester College (romero@macalester.edu).

Symposium: "Amazonian Herpetofauna." *Organizers*: Ermelinda Oliveira, Universidade Federal do Amazonas (ermeoliveira@uol.com.br); Richard C. Vogt, INPA.

SSAR Student Travel Awards: Awards of US $400 each are available. An applicant must be a student and a member of SSAR. Refer to page 243 of the December 2002 issue of *HR* for details.

Student Paper Awards: Henri Seibert prizes (US $200 each) will be awarded in five categories: Systematics, Ecology, Evolution, Conservation, and Physiology/Morphology. Refer to the official Meeting Announcement for details and to *HR* 28(4):175 for recommendations to students entering the Seibert competition.

Social Activities: General Reception, Graduate Student Reception, Picnic, Joint Meeting Banquet, SSAR/HL Silent Auction.

Field Trips: Several post-meeting field trips into the Amazon are planned. Refer to the meeting website for details.

Live Animal Exhibit: A large sample of reptiles and amphibians native to the Amazon region on display and available to photographers.

Costs: Preregistration (until 28 February) US $240 regular, $80 student, $110 accompanying person. From1 March–25 June 2003, costs are $290, $130 student. After 25 June, $340 regular, $180 student. Registration information available at:
<http://www.aiha.org.br/reginfo.html>

Further Details: Refer to the official Joint Meeting website (www.aiha.org.br) for additional details, including travel requirements to Brazil.

About Our Cover: *Varanus baritji*

The family Varanidae comprises ca. 58 species (Böhme 2002. Checklist of the Living Monitor Lizards of the World [Family Varanidae]. Report prepared for CITES, 12th Meeting of the Conference of the Parties. 44 pp. PDF file available from: www.cites.org/common/cop/12/docs/ESF12i-06A.pdf), though that number varies considerably as there is disagreement regarding the taxonomic status of several forms, and new discoveries continue to be made (e.g., *Varanus juxtindicus* of the Solomon Islands; Böhme et al. 2002. Salamandra 38[1]:15–26). The most famous member of the family is the Komodo Dragon (*V. komodoensis*), the world's largest living lizard, which can attain a total length of 3 m. However, a fossil varanid from Australia is known to have reached 7 m TL and was likely contemporaneous with early Aboriginal people (King and Green 1999. Goannas: The Biology of Varanid Lizards. University of New South Wales Press, Sydney. 116 pp.).

Varanids achieve their greatest diversity in Australia—about 30 described species—most of which are endemic to that continent. The Australian varanid radiation has been especially impressive, with medium-sized (e.g., *Varanus glebopalma*, ~1 m TL) to large (e.g., *V. giganteus*, ~2 m TL) species occupying ecological positions filled elsewhere by mammalian carnivores, together with a number of smaller species, some of which are only 25–30 cm TL as adults. Maximal species diversity occurs in northern Australia, with regional associations of 8–11 species possible in northern reaches of both Western Australia and Northern Territory (Sweet 1999. Mertensiella 11, pp. 317–366).

Among the northern Australian endemic species is *Varanus baritji* (Black-spotted Ridge-tailed Monitor, among other common names), with a fairly restricted distribution from northeast Arnhem Land west to near Darwin and then south to the Katherine region, Northern Territory. The range approaches, but apparently does not overlap that of *V. acanthurus*, its sister species (Ast 2001. Cladistics 17:211–226). This species was described relatively recently (Horner and King 1987. Records of the Northern Territory Museum of Arts and Sciences 4[1]:73–79) and is named after Neville White, collector of the type specimen ("baritj" means "white" in one of the central Arnhem languages). Among regional aboriginal languages, this species is known as "Birram" in Kunwinjku, "Birrem" in Gundjeihmi (probably the same in Gagadju), and possibly "Bohlurr" in Kune (S. Sweet, pers. comm.).

V. baritji is a small species (to ca. 60 cm TL), restricted to rocky outcrops (of sandstone, shale, limestone, or basalt), typically in open woodland, where they construct shallow burrows under large, usually well-embedded rocks. They seem to be specialized predators on large therophosid spiders (Sweet 1999, *op. cit.*). Commonly, *V. baritji* co-occurs with the following species of *Varanus*: *glebopalma, scalaris, tristis, gouldii*, and *panoptes*, and occupies the same ecological role that *V. acanthurus* or *V. storri* would fill with this same complement of species elsewhere (S. Sweet, pers. comm.). Males are often more brightly colored and more distinctly marked than females, and both sexes possess bright lemon-colored chins and throats. Specimens from the western Arnhem Land region are very dark in comparison to animals from other areas. Breeding takes place during the dry season. Females produce clutches of 3–12 eggs, which in captivity have hatched in a little over 100 days. Hatchlings are very similar to those of *V. acanthurus* but lack the neck striping typical of that species (G. Husband, unpubl.).

Our cover photo was taken by **Paul Freed**, supervisor of the Herpetology Section and a 23-year veteran of the Houston Zoo. Over the last three decades, Paul has done fieldwork for Conservation International, the Carnegie Museum of Natural History, Louisiana State University, and the Raleigh State Museum, as well as his own research on herpetological parasitology. Additionally, Paul has amassed over 40,000 images of animals, plants, habitats and people during this time. Examples of his photography can be viewed at: www.freedsphotography.com.

Freed photographed the cover subject, an unsexed adult *V. baritji* ca. 30 cm TL, *in situ* ca. 75 km E of Katherine in Australia's Northern Territory. He used a Canon F-1 with a 100mm f/4.0 macro lens along with a Canon Macrolite ML-1 flash, recording the image on Fuji Velvia film.

Editor's note.—Special thanks to Sam Sweet, Grant Husband, and Steve Wilson for sharing unpublished observations of *V. baritji*.

SSAR BUSINESS

SSAR Henri Seibert Award for 2003

The Henri Seibert Award was initiated in 1992 to provide recognition for the best student papers given at the annual meeting of the SSAR. To be eligible, the presented paper must be the results of research conducted by the presenter. The research must have been done while the student was in either an undergraduate or graduate degree program. The presentations will be judged by the SSAR student prize committee. One Seibert Prize of US $200 may be given in each of the following five categories: Conservation, Ecology, Evolution, Physiology/Morphology, and Systematics. Consult *Herpetological Review* 28(4):175 for recommendations to students entering the Henri Seibert competition (also available on the SSAR web site at:

http://www.ukans.edu/~ssar/seibert.html

Students entering the competition must be members of SSAR. Students can win the Henri Seibert competition only once. Please indicate the category to which you are submitting your abstract on the abstract form in the Call for Papers.

Kennedy Student Award Committee Annual Report—2002

The Kennedy Award Committee (Robin Andrews, Diana Hews, Terry Schwaner, Lynnette Sievert, Robert Gatten, Chair) has completed its work for Volume 35 of the *Journal of Herpetology*. The Committee has selected "Effects of prolonged retention in hatcheries on green turtle (*Chelonia mydas*) hatchling swimming speed and survival" by **N. J. Pilcher** (student) and S. Enderby (Vol. 35:633–638). The Kennedy Award carries with it a cash prize of US $200 or the winner's selection of any SSAR publications valued at twice that amount.

The Committee encourages each student member of the Society to submit their work to the *Journal*, and encourages each regular member who supervises the work of students to encourage his/her students to submit their work to *JH*.

SSAR Presubmission Manuscript Reviews

The SSAR Board of Directors received a proposal at its Kansas City meeting in July 2002 from Richard Wassersug to facilitate the preparation and submission of manuscripts from colleagues whose primary language is not English. This proposal was adopted enthusiastically, and is summarized below.

English is the language of science communication and of the SSAR. Ironically, though, most of the animals that we study come from countries where English is not the first language. In order to promote the publication of research on amphibians and reptiles from those countries, the SSAR has started an editorial assistance program for herpetologists who do not have English as their first language.

Various members of the SSAR community have offered to read and edit up to three English language manuscripts per year within their specific area of herpetological expertise. This is a free service provided to herpetologists whose first language is not English, but who are striving to publish their findings in peer-reviewed English language journals. The people who are volunteering to edit manuscripts are not formally working for the SSAR and their assistance is no guarantee that your paper will be accepted in the English language press. For additional details, as well as a list of volunteering herpetologists and their areas of expertise, please consult the SSAR web site at:

<http://www.ukans.edu/~ssar/presub.html>

SSAR Student Awards Fundraiser: 2002 Results and Call for 2003 Donations

Thanks to the many generous donations from several individuals to the 2002 silent auction at Kansas City, the SSAR Student Travel Awards Committee (SSAR STAC) awarded 10 US $200 travel grants to students presenting papers or posters at the meetings. The SSAR STAC wishes to thank all who donated items to the 2002 silent auction.

The Eighth Annual Frameable Art Silent Auction at Kansas City raised over $1800.00 for future student travel awards. On behalf of the SSAR, thanks to all who helped including, Christina Loper and Gary Lechner, California State University, Chico, and Andre Ngo, University of Toronto. Special thanks for a job well done to the SSAR STAC Co-chairs, Glen Lubcke and Jack Campbell.

The SSAR STAC announces the Ninth Annual Frameable Art Silent Auction to be held at the 2003 SSAR meeting at Manaus, Brazil. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please contact: *Dawn Wilson, Biology Department, California State University, Chico, Chico, California 95929, USA; e-mail: dwilson@csuchico.edu; tel. 530-898-6303.*

SSAR Student Travel Awards Call for Applications

For the Brazil meeting, awards of US $400 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author of a paper or poster to be presented. Application package must include: 1) letter signed by his/her major advisor or department chair that states: he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. Qualified applicants are pooled and winners are drawn at random. Students from local meeting site and current members of the SSAR Travel Awards Committee are excluded from applying for a travel award. **APPLICATIONS MUST BE POSTMARKED BY 1 MAY 2003.** Award checks will be disbursed at the meeting. Direct requests for information to: *Dawn Wilson, Biology Department, California State University, Chico, Chico, California 95929, USA; e-mail: dwilson@csuchico.edu or tel. 530-898-6303.*

NEWSNOTES

CITES Nomenclature Committee To Use *Amphibian Species of the World*

Notifications to the Parties, Standard reference for amphibians:

1. Decision 11.167 regarding the nomenclature of CITES-listed species requires the Secretariat to make a print-out of the standard reference seven months before every second meeting of the Conference of the Parties, starting with the 12th meeting of the Conference of the Parties, and to submit the print-out for review and adoption by the Nomenclature Committee.

2. At its meeting of 8 April 2002 (San José, Costa Rica), the Nomenclature Committee accepted the print-out of *Amphibian Species of the World* by D. R. Frost as the standard reference for amphibians, valid as from the date of distribution of this Notification to the Parties. The pertinent pages regarding CITES-listed species of amphibians, the Amphibian Species Checklist, are provided in annex.

3. It should be noted that the layout of the website where the on-line version of *Amphibian Species of the World* can be found (http://research.amnh.org/herpetology/amphibia) looks different from the printed version adopted by the Nomenclature Committee. The content is however identical.

This notification was distributed 4 October 2002.

<http://www.cites.org/eng/notifs/2002/058.shtml>

Southwestern Research Station Positions and Grants for 2003

VOLUNTEERS—Approximately 30 volunteer positions are open in 2003 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals. The program is open to non-students as well, particularly in the spring and fall.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers

A New Facsimile Reprint from the Society for the Study of Amphibians and Reptiles

The Herpetology of Cuba

by Thomas Barbour and Charles T. Ramsden

Barbour and Ramsden's *The Herpetology of Cuba*, published in 1919, was the first complete listing of the amphibians and reptiles of Cuba to include detailed descriptions of all species. More than 80 years after its original publication, the work remains an essential reference on the systematics, natural history, and biogeography of the herpetofauna of the largest and most diverse of the islands of the West Indies. *The Herpetology of Cuba* is among the most important of Barbour's more than 200 herpetological publications and draws on the extensive field experience of both authors over many years throughout the island

Detailed accounts are provided for 70 species including 12 frogs and toads, 40 lizards, 2 amphisbaenians, 13 snakes, 1 turtle, and 2 crocodiles. Among these are five new species descriptions (2 *Sphaerodactylus* and 3 *Anolis*). Sixty-eight of these species are illustrated by 95 figures on 15 plates.

The Herpetology of Cuba, originally published in the Memoirs of the Museum of Comparative Zoology at Harvard College, has long been out of print. With the publication of the new SSAR facsimile edition this classic book is again available to herpetologists with interests in Cuba, the West Indies, or island herpetofaunas in general. A foreword by Rudolfo Ruibal of the University of California, Riverside places *The Herpetology of Cuba* in its historical context and a listing of the current names for Barbour and Ramsden's species facilitates use of the book by modern workers.

Specifications: 200 pages, 8.5 x 11 inches, 15 plates, clothbound. ISBN 0-916984-61-3. To be published March 2003.

Prices and Shipping Costs: Pre-publication to SSAR members US$45 (before 31 March 2003); Institutions, non-members $55 • *Shipping*: USA address, add $4; Canada and Mexico, add $7; all others add $9.

Send Orders To: Breck Bartholomew, P.O. Box 58517, Salt Lake City, Utah 84158-0517, USA (*telephone and fax*: area code (801) 453-0489; *e-mail*: ssar@herplit.com). Please make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may also be charged to MasterCard, Discover, American Express, and Visa (Please provide the account number and card expiration date). SSAR membership information and a complete list of all Society publications can be obtained from www.herpsoc.org or Mr. Bartholomew.

(September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, P.O. Box 16553, Portal, Arizona 85632, USA; phone/fax: 520-558-2396; e-mail: swrs@amnh.org.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately US $400–$800 to graduate or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by contacting: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024-5192, USA; http://research.amnh.org/grants/index.html; e-mail: grants@amnh.org. Application due date: February 15, 2003.

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 2003 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson

2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include *in situ* behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.

3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on an herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president.

5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.

6. INTERNATIONAL. Proposals may address needs in any of the above five categories, but applicants must be from countries where herpetological research has historically been underfunded, and where alternate sources of financial support are scarce or nonexistent.

7. BIBLIOGRAPHIC RESEARCH. This special category continues for 2003 thanks to a donation from Itzchak and Carolyn Gilboa. Proposals should address a major need to consult library or other information resources. The project must focus on a herpetological topic. Proposals from individuals only, accompanied by a letter of support from someone knowledgeable about the applicant and about the importance of the project.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be students AND members of the SSAR with the exception of those applying for support of regional herpetological society projects, or those applying in the international category. Membership dues must be paid (to SSAR Treasurer) no later than 31 December 2002 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. Past recipients of an SSAR GIH award in any category are not eligible for future awards. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) TITLE PAGE giving the title of the project, the name, mailing address, office and home telephone numbers and, if possible, fax number and e-mail address of the applicant. The title page should include a statement indicating that applicants "will comply with all applicable permit regulations, and adhere to all appropriate animal care guidelines in the course of conducting funded projects." (B) BACKGROUND AND OBJECTIVES of the proposed project. (C) METHODS of carrying out the project. (D) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). Include an explicit explanation of how an SSAR award of $500 would be applied toward the objectives of the project, and provide a listing of all current and pending support for the project. (E) BRIEF RESUMÉ of the applicant or project coordinator. (F) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed 1200 words, excluding title page, literature cited, resumé, and budget. Applicants must indicate word count on their application.

Applicants must designate to which of the seven categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than **28 FEBRUARY 2003** to be considered. Failure to meet these guidelines may result in elimination of a proposal from consideration. The awards will be announced on or around 1 April 2003. Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Erik R. Wild, Chair, SSAR Grants-in-Herpetology, Department of Biology, University of Wisconsin - Stevens Point, Stevens Point, Wisconsin 54481-3897, USA. Tel. (715) 346-4269; Fax (715) 346-3624; e-mail: ewild@uwsp.edu.*

Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA; phone/fax: 520-558-2396; e-mail: swrs@amnh.org.*

MEETINGS

Meetings Calendar

19–23 January 2003—Sixth Latin American Congress of Herpetology (Congreso Latinoamericano de Herpetología), Museum of Natural History, Universidad Nacional Agraria, La Molina, Lima, Peru. Information: http://barrioperu.terra.com.pe/VICLAH/.

21–23 February 2003—The Desert Tortoise Council 28th Annual Meeting and Symposium, Las Vegas, Nevada, USA. Information: http://www.deserttortoise.org/symposium/2003/index2003.html.

18–22 June 2003—Second International Congress on Chelonian Conservation in Senegal. Conference to be held in English w/ French translations. Information: www.tortues.com; e-mail: soptom@soptom.com.

26 June–1 July 2003—46th Annual Meeting, Society for the Study of Amphibians and Reptiles, together with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists. Hotel Tropical, Manaus, Brazil. Details available elsewhere in this issue and from the meeting web site: http://www.aiha.org.br/.

3–6 September 2003—International Herpetological Symposium, 27th Annual Meeting, Houston, Texas, USA. Information: http://www.kingsnake.com/ihs/index.html.

OBITUARIES

James Kezer, Pioneer in Amphibian Cytogenetics and Teacher Extraordinaire 1908–2002

STANLEY K. SESSIONS
Department of Biology, Hartwick College
Oneota, New York 13820, USA
e-mail: SessionsS@Hartwick.edu

Jim Kezer, amphibian cytogeneticist and professor emeritus, University of Oregon, died at home on January 3, 2002, from causes associated with age. He was 93. Jim (or Kezer, as he was affectionately known to many) was loved and admired by friends and colleagues throughout the world, not only as a pioneer in amphibian cytogenetics, but also as a master teacher who had an almost magical influence on anyone he encountered.

Jim's interests and work bridged worlds. He was both an accomplished musician as well as biologist, researcher as well as teacher, naturalist and cytologist, comfortable in both laboratory and field. His publication record reflected this blend, ranging from life history patterns to molecular cytogenetics. He produced a solid record of accomplishments, in teaching, in research, in fighting for the preservation of wilderness, and in presenting innumerable lectures to the public in order to convey the wonders of science. His scientific contributions include: the first application of the "squashing" technique to vertebrate chromosomes, allowing the first accurate chromosome counts in numerous species of salamanders; the discovery of karyological uniqueness in proteid salamanders; pioneering work on the molecular organization of amphibian chromosomes; the discovery of multinucleated oocytes (unique among vertebrates) in the Tailed Frog (*Ascaphus truei*); the discovery of chromosomal polymorphisms in plethodontid salamanders of the genus *Aneides*; and the discovery of strongly heteromorphic X/Y sex chromosomes in tropical bolitoglossine salamanders. He and his work have had an important influence on both herpetology and cytogenetics.

L. James Kezer was born on October 17, 1908 at 716 Duck Street in Stillwater, Oklahoma, to Charles and Lulu James Kezer. He developed an interest in science early on and attended the University of Iowa as an undergraduate, earning his bachelor's degree in 1930. If it hadn't been for the Great Depression, Jim would probably have gone to work for an electric company, and the field of biology would never had experienced this legendary figure. In a fortunate twist of fate, he instead obtained a job as high school science teacher in Summit, New Jersey, teaching physics, chemistry, and biology.

During summers, when he was not teaching high school, Jim worked on his Masters degree at Cornell, and took a course on Natural History of the Vertebrates with A. H. Wright. It was in this course that Jim was first introduced to plethodontid salamanders. Jim once described to me the precise moment: During a field trip into Cascadilla Gorge near the Cornell Campus, Wright lifted a piece of bark, exposing several specimens of red-backed salamanders (*Plethodon cinereus*), and *click!* Kezer was hooked. The experience inspired Jim to incorporate field trips into his high school science classes, engaging students in surveys of vertebrate animals in the Watchung Reservation and other localities near Summit. Jim earned his Master's degree at Cornell in 1937 with Wright and W. Hamilton as his co-advisers.

Jim continued at Cornell, working on his PhD with Wright and, after Wright's retirement, E. C. Raney. A cytology course gave Jim the idea to focus his PhD research on salamander chromosomes, especially plethodontid salamanders, about which little was known. Animal cytogenetics at that time involved paraffin sections, which turned out to be a completely inadequate technique for the large chromosomes of salamanders. Jim learned about the "squash technique" in a botany course (some plants have large chromosomes too), tried it on salamanders and the results were astounding. Soon he had accurate chromosome counts for several species of plethodontids, obtained from squashes of meiotic cells from testes. (It is a remarkable fact that Jim determined accurate counts of chromosome complements in several species of salamanders years before the correct chromosome number in humans was known.)

Jim's graduate work was interrupted by World War II, and he

enlisted in the U.S. Army, rising from buck private to captain and head of bacteriology and serology at the 55th General Hospital in England and France during the years 1943-1946. It was in France, apparently, that he was introduced to what would become a lifelong love of opera. His first salamander paper was published in *Copeia* in 1944.

After the war Jim returned to Cornell to work on the chromosomes of plethodontid salamanders, winning a Stoye Award from the ASIH, and finishing his PhD in 1948. His first college teaching job was at the University of Missouri, where he taught courses in General Zoology, and in the summer worked as park naturalist at Crater Lake National Park, in Oregon. At Crater Lake, Jim began to work on western species of amphibians, including the Long-toed salamander, *Ambystoma macrodactylum*, and the Oregon Rough-skin newt, *Taricha granulosa*. It was also at Crater Lake that Jim met Ralph Huestis, who was chair of the biology department at the University of Oregon. Huestis was able to lure Jim away from the University of Missouri to take a position at the University of Oregon in 1954.

At the University of Oregon, Jim quickly built a reputation as master teacher, organizing curricula, inventing new laboratory exercises and producing laboratory manuals for General Biology in a program designed to enhance undergraduate science education and funded by a grant from the Ford Foundation. He also began to teach such courses as cell biology, histology, and cytology, and he was a highly effective and popular teacher. Once he had secured his position at the University of Oregon, Jim also began to pursue his chromosomal research in earnest, most of it funded out-of-pocket. In 1956 and again in 1960, Jim traveled to Europe in quest of *Hydromantes* from Italy and Sardinia (the only European plethodontids), and the European Cave Salamander, *Proteus anguinus,* from the caves of the former Yugoslavia. His vivid written and oral accounts of these trips are famous among his family, friends, and colleagues. At that time such expeditions were quite dangerous, and required armed soldiers to protect him from bandits. This work culminated in the first accurate chromosome count for *Proteus*, which he found to have exactly the same chromosome number as the North American Mudpuppy, *Necturus maculosus*, a chromosome number not found in any other salamanders. He and his coauthors, Takeshi Seto (Hokkaido University in Japan) and Charles Pomerat (Pasadena Foundation for Medical Research), realized that this was strong evidence that, despite their disjunct geographic distribution, *Necturus* and *Proteus* form a monophyletic lineage, rather than being an example of convergent evolution as some believed, and published the results in *The American Naturalist* in 1965.

Jim's interest in ever more detailed analyses of chromosome structure in salamanders led him to visit Joe Gall's lab in Minnesota to learn how to prepare lampbrush chromosomes from salamander ovaries. Through Gall he became acquainted with the leading lampbrush chromosome researcher in the world, Mick Callan, at St. Andrews University in Scotland. Jim soon became one of the world's experts on "lampbrushology," introducing this technology to the University of Oregon (see www.le.ac.uk/biology/lampbrush/people), and using it to study detailed chromosome structure in a wide variety of salamander species that had never before been studied in that way. Later, he began a series of collaborations with molecular biologists, including Herbert Macgregor

FIG. 1. Jim Kezer flanked by the brothers Ceron (Miguel on the left, Carlos on the right), on a trip to Mexico in 1974 with Jim Lynch and Charles Kimmel.

(University of Leicester in England) and Pedro León (now at the University of Costa Rica), producing papers on the chromosomal localization of specific kinds of DNA sequences in plethodontids as well as certain other groups of salamanders.

Most of Jim's early cytogenetic research was focused on north temperate species of plethodontids which had nearly identical karyotypes in terms of chromosome number and morphology (n = 14 pairs of all-biarmed chromosomes). He finally found an exception to this karyological uniformity when he made some squashes of Oregon *Batrachoseps*, a bolitoglossine salamander with n = 13 pairs of chromosomes. This was an astonishing discovery since the only other bolitoglossines he had examined were species of *Hydromantes* from Europe and California, which all have 14 pairs of chromosomes. At this point Jim became determined to examine more bolitoglossines, most of which are neotropical, so he organized trips to Mexico and Costa Rica that began with his sabbatical year in 1962.

His first trip, in July 1962, involved driving solo in his VW beetle all the way through Mexico and into Central America. This trip resulted in the "rediscovery" of two of the most famous amateur Mexican herpetologists ever known: the brothers Carlos and Miguel Ceron of Cuatlapán in Veracruz, who as teenagers had collected amphibians and reptiles for Hobart Smith and Edward Taylor (Fig. 1). As Jim tells the story, he was searching for salamanders beneath the leaves of red banana plants on July 15 when two local men came up to him and asked him if he knew Smith and Taylor. Carlos and Miguel Ceron subsequently became indispensable guides for many herpetologists in search of Mexican species, and the relationship between Kezer and the Cerons lasted for many years. Jim returned in 1982, his last trip to Mexico, to celebrate the 20th anniversary of the "rediscovery" of the brothers Ceron. Carlos Ceron died from cancer just last year.

In Costa Rica Jim worked with Douglas Robinson, of the University of Costa Rica, who helped him obtain specimens of *Oedipina*, among other bolitoglossines. He finally hit the jackpot, first discovering heteromorphic X/Y sex chromosomes in *Oedipina* during a visit to Callan's lab in Scotland in 1963, and soon after discovering similar sex chromosomes in the Mexican genus *Thorius*. Other discoveries included reciprocal translocations in

Thorius and *Lineatriton*, and supernumerary chromosomes in *Oedipina*, *Thorius*, *Lineatriton*, and *Chiropterotriton*. Jim made a total of sixteen visits to Latin America between 1962 and 1982.

Among the other important discoveries was the finding of chromosomal polymorphisms involving pericentric inversions in the plethodontid genus *Aneides*. This research (on which I was fortunate enough to be a collaborator) began with Oregon populations of the Clouded Salamander, *A. ferreus*, and eventually expanded to include all known species of the genus. One of the important outcomes of this research was the recognition that "*A. ferreus*" included two chromosomally distinct groups of populations. These groups have since been confirmed biochemically as two distinct species by one of David Wake's students.

Jim Kezer was one of the truly legendary characters of the University of Oregon. I do not remember when I first heard about him, but I do remember the first time I experienced one of his famous lectures. It was in Edward Novitski's evolution course. Novitski asked Jim Kezer to give a guest lecture, and Jim's lecture was on the chromosomes of plethodontid salamanders. I was spellbound as Jim took us all with him (metaphorically speaking) to Mexico and Central America to search for bolitoglossine salamanders for cytogenetic research. First an introduction to the Family Plethodontidae, and to the "masterful research by the world's leading expert on plethodontid salamanders," David B. Wake. "Plethodontid salamanders, don't you know, spread from the Appalachian region of eastern North America, on down into eastern Mexico, Central America, and on into Brazil. We've just got to look at the chromosomes of this marvelous group! Come on class, let me take you with me to Mexico and Costa Rica, where we will search for cytological treasures in *Bolitoglossa*, *Pseudoeurycea*, *Lineatriton*, *Parvimolge*, *Chiropterotriton*, *Thorius*, and, of course, *Oedipina*!" One of the truly remarkable things about the chromosomes of these salamanders is their large size, which greatly facilitates analysis of chromosome structure and behavior during meiosis. The large chromosomes of *Oedipina* in particular allowed an unobstructed view of the intimate interactions of the X and Y sex chromosomes (Fig. 2). It was a clever and effective way to introduce students to the concepts of meiosis and the evolution of sex chromosomes.

I did not meet Jim Kezer in any personal way until later, when Chuck Kimmel (U. of O. Neurobiology Institute), for whom I was working as lab technician, took me upstairs and down the hall into the old science building to meet him. As we approached his office+lab (rooms 312 and 313), I could hear the humming of opera along with the clinking of jars and bottles: we had arrived in time to find Jim cleaning and feeding his live collection of salamanders. Salamanders of all kinds were housed in gallon jars arranged on a large water table in his very small lab. An old Zeiss photoscope, complete with phase contrast and optivar lenses, was conveniently located next to a refrigerator, and next to that a Zeiss inverted microscope, and next to that a dissection stereomicroscope for making lampbrush chromosome preps. The mild fumes from fly medium (here *Drosophila* fruitflies were used only for salamander food), ivory soap (an old bar always sitting in a dish next to the sink), and photographic fixer mixed to create a signature odor, pleasantly familiar to all the students who ever worked in Kezer's lab.

A small man with short-cropped white hair, square jaw, and

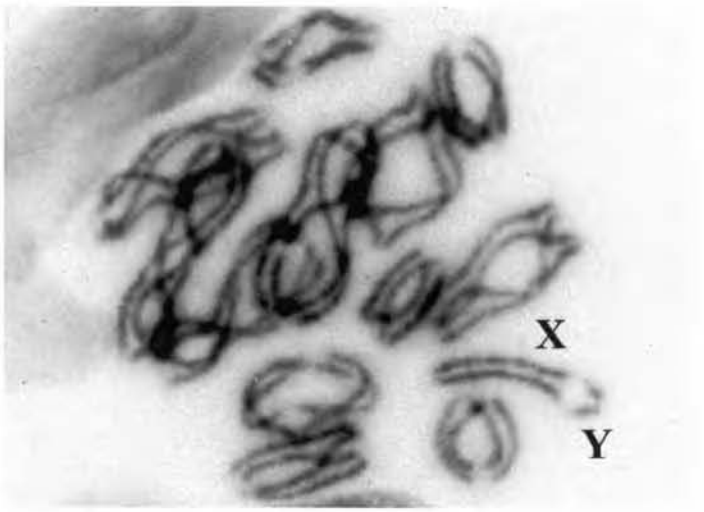

FIG. 2. The chromosomes of the Costa Rica bolitoglossine salamander, *Oedipina uniformis*, at diplotene stage of prophase of the first meiotic division. The X and Y chromosomes, still attached at their ends, are indicated.

mirthful eyes, dressed in workman's sky blue shirt (sleeves rolled up past the elbows) and dark blue Dicky's pants with polished black work shoes, Kezer did not look at all like a typical professor. In fact, Kezer resembled someone from the physical plant, an impression reinforced by his habit of emptying his own trash cans. Once he was mistaken for a janitor by a new chemistry professor who complained that his trash cans needed emptying too. In true Kezerian fashion, Jim happily and genuinely agreed to empty his trash cans right away, and then introduced himself. Needless to say, the chemistry professor was a bit embarrassed!

Kezer welcomed us into his lab. He immediately engaged us in all sorts of interesting adventures, examining the salamanders on his watertable, perusing some recent photomicrographs, leafing through some reprints sent by a colleague, and, of course, peering through the microscope at some "cytological treasure." "Come and sit down and feast your eyes on something truly marvelous. Do you see it? Do you see how the bivalents are arranged? Come on tell me: what stage is it? Why, it is a diplotene of the first meioic prophase, of course! I don't know how we do it, but we do it!" Never had I experienced so much activity and enthusiasm occurring in such a small space and with such intensity. I decided on the spot to become his student.

As I got to know him better, I realized that Jim led a "streamlined" life organized around four main things: salamanders, chromosomes, opera and, most importantly, people. Once having played the violin quite well (as a graduate student, he had been concertmaster for the Cornell University orchestra), he had given it up in favor of the art of listening. His home (2410 Emerald Street) was conveniently located only a mile from campus, and was basically a studio for listening to music, complete with a set of huge "magnaplanar" speakers and a computerized delay system to mimic the sounds of a large concert hall. He lived alone, but often entertained guests with "gala occasions" featuring opera plus plenty of ice cream and strawberries. He was a familiar sight in Eugene, commuting between home and lab via bicycle.

Jim retired from the University of Oregon in 1974, and unlike most new retirees, immediately and vigorously launched a new

phase of his professional career. It is very telling that nearly half of his publications were produced after his retirement, and most of them were based on new research findings. He also continued to be active in various organizations and especially the Eugene Natural History Society. Jim was widely admired, but he had the unique ability to turn the tables, making each person he met feel like a million bucks, as if they were the center of the universe. Thus it is impossible for anyone who has met him to forget him. Jim will always be remembered as a person who loved science and teaching and, most of all, people.

A recent gathering of Jim's closest friends and colleagues in Eugene, Oregon was hosted by Charles and Reida Kimmel (University of Oregon) and Jay and Teresa Bowerman (SunRiver Nature Center), and the participants included Pedro Leon, Takeshi Seto, David Wake, and several other scientists, including me. We took Jim's ashes to one of his favorite salamander collecting sites. Each of us took a handful of ashes and scattered them in the forest. It was a fitting tribute to such a fine biologist and teacher.

Acknowledgments.—This obituary benefitted from interactions with John Applegarth, Jim Baldwin, Jay Bowerman, and Charles Kimmel, as well as from an essay written by Will Eaton in *Nature Trials* (vol. 17, number 2, February 1983), published by the Eugene Natural History Society.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **Omar Torres-Carvajal**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Chemistry of Paracloacal Secretions of the American Crocodile

Paracloacal glands of crocodilians produce pheromones involved in nesting and mating behaviors. The authors used gas chromatography-mass spectrometry to study the chemistry of paracloacal gland secretions of the American crocodile (*Crocodylus acutus*). Identification of major components was supported by infrared spectra obtained with gas chromatography-Fourier transform IR spectroscopy. Secretions were obtained from individuals at three farms in Florida by manually pressing the region around the cloaca. Among the compounds found were many aliphatic acetates, butyrates, formates, free alcohols, and several hydrocarbons. This is the first time that formates are reported from reptiles. Precloacal-secretion chemistry of crocodiles has been previously studied only in the African dwarf crocodile *Osteolaemus tetraspis*. Interestingly, there are substantive chemical differences in the paracloacal gland products between *Crocodylus* and *Osteolaemus*. The authors conclude that more taxa need to be examined in order to assess the range of chemical variation within Crocodylidae.

García-Rubio, S., A. B. Attygalle, P. J. Weldon, and J. Meinwald. 2002. Reptilian chemistry: volatile compounds from paracloacal glands of the American crocodile (*Crocodylus acutus*). Journal of Chemical Ecology 28(4):769–781.

Reproductive Performance of *Vipera aspis*

The reproductive performance of living organisms is affected in part by environmental factors. Species that use storage as the primary energy source for reproduction are known as capital breeders, whereas species that use energy from current food intake are known as income breeders. Infrequent reproduction has been observed among capital breeding reptiles, such as viperid snakes. The authors studied how temperature and food availability affects reproductive performance in the aspic viper, *Vipera aspis*, in west-central France. More than 400 females were marked with passive integrated transponder tags from 1992–2000. Level of fat stores was estimated by calculating initial body condition (mass relative to length), and prepartum mass change was used as an indicator of food intake during reproduction. The authors found that female *Vipera aspis* benefited from energy storage to reproduce succesfully; however, reproductive output also was limited by prey availability. Additionally, mass gain was affected by mean environmental temperature during the active season. This study demonstrates that reproductive performance of the aspic viper is determined not only by capital breeding, but also by income breeding.

Lourdais, O., X. Bonnet, R. Shine, D. Denardo, G. Naulleau, and M. Guillon. 2002. Capital-breeding and reproductive effort in a variable environment: a longitudinal study of a viviparous snake. Journal of Animal Ecology 71:470–479.

Social Experience Affects Behavior in Leopard Geckos

Social inateractions affect the behavior and physiology in a variety of organisms. The authors investigated the effects of social experiences in adulthood on behavioral phenotype of male leopard geckos (*Eublepharis macularius*) by comparing behaviors of socially experienced and naïve geckos. All males were reared in isolation until sexual maturity (1–1.5 years). Subsequently, 11 males were placed for 1–2 years in individual, isolated cages, whereas 10 males were placed in cages containing 3–4 sexually mature females. Behavioral differences between the two groups of males were examined when males were gonadally intact, following castration, and following androgen replacement. Activity, territoriality, and courtship behaviors were observed by placing the males in test arenas (both empty and with females). Experienced males displayed more territoriality and activity than naïve males before and after castration, which suggests that territorial behavior could be androgen independent. No significant courtship behavior differences were found after castration; however, experienced males showed more courtship behavior than naïve males following androgen replacement. The results indicate that social experience in male leopard geckos influences courtship and territorial behaviors.

Systematics of *Scinax*: How Many Species Groups?

With 84 recognized species, *Scinax* is the second largest genus within Hylinae. It ranges from southern Mexico to eastern Argentina occupying all major tropical and subtropical areas. Although five species groups have been proposed, the phylogenetic relationships among species of *Scinax* have not been ascertained yet.

In an attempt to test the monophyly of each of the five species groups and analyze the relationships among them, Faivovich made a cladistic analysis of 36 species of *Scinax* including seven outgroup taxa. Using NONA 2.0, the author performed a parsimony analysis including 86 characters of internal and external morphology of larvae and adults. A strict consensus tree was calculated from 36 most-parsimonious trees. Interestingly, Faivovich found that all of the conflict among the most-parsimonious trees was localized among species of two species groups—*Scinax rubra* Group and *S. catharinae* Group. Bremer support and parsimony jackknifing indicated that only two species groups were well supported—*Scinax catharinae* Group and *S. rostrata* Group. Based on the topology of the strict consensus tree, the author suggests to keep the *S. catharinae* Group. In addition, a *S. rubra* clade that includes *S. acuminata* and *S. rostrata* clades is proposed. Nonetheless, monophyly of the *S. rubra* clade needs to be corroborated with increased character and taxon sampling.

Monkeys Also Are Frog-Spawn Predators

Most anuran families include species that breed terrestrially. Although these species avoid predation in aquatic environments, terrestrial clutches are still under predation pressure. The authors discovered a few species of monkeys that feed on foam nests and exposed frog clutches in the Taï National Park, Ivory Coast. Sooty mangabeys (*Cercocebus torquatus atys*) were found to check the vegetation intensively around ponds for exposed clutches of *Hyperolius chlorosteus* and *H. sylvaticus ivorensis* and foam nests of *Chiromanctis rufescens*. Most of the monkeys that fed on these frog clutches were adult females. Additionally, the authors also observed diana monkeys *Cercopithecus diana diana* feeding on *C. rufescens* foam nests. Rödel et al. suggest that sooty mangabeys feed on frog clutches because these monkeys face a period of food shortage during the rainy season, which is when frog terrestrial clutches are available and easy to harvest. Further research is needed in order to determine the impact of monkey predation on frog clutch survival and the energetic value of this food item for monkeys.

Ecological Speciation in Scincid Lizards

Ecological speciation results from the evolution of reproductive isolation as a consequence of divergent natural selection. To determine if ecology actually plays a major role in speciation, the authors studied 54 populations of skinks of the *Eumeces skiltonianus* Group, which extends from southwestern Canada into Baja California. *Eumeces skiltonianus* and *E. lagunensis* are small, striped lizards that live in mesic and cool habitats, whereas *E. gilberti* is represented by large and uniform-colored lizards that occur in warmer and drier environments. The first step in this study was to perform a phylogenetic analysis of mtDNA using parsimony and maximum likelihood methods. Results supported monophyly of the *skiltonianus* Group and demonstrated parallel origin of three clades characterized by the *gilberti* morphotype; *E. lagunensis* was among *E. skiltonianus* populations. The second step was to evaluate evolutionary changes in body size and color pattern by mapping characters onto the reconstructed phylogeny. The authors found that *E. gilberti* lineages were clearly defined by large body size and ontogenetic color change (i.e., from striped to uniform-colored), whereas retention of stripes and smaller size characterized clades of *E. skiltonianus* and *E. lagunensis*. Parallel evolution of the *gilberti* morphotype was strongly supported by similarity in early ontogenetic trajectories and close association between differences in body size and color pattern.

RICHMOND, J. Q., AND T. W. REEDER. 2002. Evidence for parallel ecological speciation in scincid lizards of the *Eumeces skiltonianus* species group (Squamata: Scincidae). Evolution 56(7):1498–1513.

Diversification of Salamanders of the Genus *Batrachoseps*

Batrachoseps is the most diverse genus of salamanders in western North America. Like other salamanders, species of *Batrachoseps* are morphologically conservative; therefore, molecular markers (allozymes) have been used in previous phylogenetic studies. In order to study the evolutionary history of this genus in more detail, the authors analyzed sequence variation in the cytochrome *b* gene of several populations representing almost all groups within *Batrachoseps* that had been described previously. The analysis included maximum parsimony, maximum likelihood, and weighted-least-squares methods. Support for nodes was estimated with (1) bootstrapping for both the MP and LS analyses, and (2) Bayesian analysis for the ML tree. Six highly supported clades within *Batrachoseps* were concordantly identified in all analyses—subgenus *Plethopsis* and five species groups within the subgenus *Batrachoseps*. Nonetheless, significant discordance regarding population relationships was found between trees found in this study (mtDNA) and trees proposed in previous studies (allozymes). The authors suggest that these discrepancies result from fragmentation of populations, allopatric divergence, and the recontact and merging of fragments caused predominantly by male-mediated gene flow. Because of greater philopatry of females and high rate of evolution of mtDNA, differences in mtDNA between geographically separated populations accumulate rapidly as species fragment. Thus, the maternally transmitted mtDNA seems to reflect deep history, while the biparentally inherited allozymic markers seem to reflect recent and current patterns of interactions

among populations.

Conservation of the Tuatara by Translocation

Translocation might be the only conservation strategy for some endangered species of terrestrial vertebrates. The only two living species of Sphenodontia are restricted to New Zealand and occupy <0.5% of their original range, and thus are among the most endangered reptilian taxa in the world. Predation by introduced mammals such as rats, dogs, cats, and mustelids is probably the major cause of decline of tuatara populations. In 1995, the authors introduced *Sphenodon guntheri* to Titi Island, a rodent-free reserve in New Zealand, and monitored the progress of this population for five years. The translocated individuals included 18 adults from the wild population on North Brother Island and 50 juveniles from eggs incubated in captivity. Monitoring consisted of six post-release visits ranging from 4–7 nights and included 3–4 people. The authors recaptured only 57% of the translocated tuatara and found that adults had gained weight following release, while juveniles showed little average weight gain. Unfortunately, no hatchlings or hatched eggs were found, but tuatara are long-lived, late-maturing species; therefore, maybe only 10% of the average generation time was monitored. In addition, cryptic appearance and elusive behavior of juveniles, and habitat inaccessibility on Titi Island are possible causes for not recapturing more individuals. Establishment of a self-sustaining population of *S. guntheri* on Titi Island might take decades to confirm.

NELSON, N. J., S. N. KEALL, D. BROWN, AND C. H. DAUGHERTY. 2002. Establishing a new wild population of tuatara (*Sphenodon guntheri*). Conservation Biology 16:887–894.

Adhesion of Gecko Setae by van der Waals Forces

Two hypotheses have been proposed to explain the mechanism of dry adhesion in the millions of setae on the toes of geckos. The first hypothesis attributes adhesion to thin-film capillary forces or other mechanisms relying on hydrophilicity, whereas the second one proposes van der Waals forces as the mechanism of adhesion. The authors tested both hypotheses by measuring adhesion on two polarizable semiconductor surfaces that varied greatly in hydrophobicity. Foot and setal adhesion of live Tokay geckos (*Gekko gekko*) were analyzed with hydrophobic and hydrophilic semiconductor wafers and microelectromechanical systems. In addition, the authors fabricated synthetic setal tips to determine if adhesive force depended on material or size of the setal tips. The results supported the van der Waals hypothesis and rejected the idea of capillary adhesion, as well as the hypothesis that water contact angle of a surface predicts the attachment forces in setae. It also was found that for a given thermodynamic adhesion energy smaller spatulae result in a greater adhesive force per unit area. Finally, the authors suggested that synthetic adhesives could be enhanced by dividing their surface into small protrusions to increase surface density, and, moreover, that humans could fabricate the first dry, adhesive microstructures using gecko setae as models.

Spermatozoa Ultrastructure in the Lizard *Ameiva ameiva*

Sperm ultrastructure has not been described in most squamate reptiles. The authors examined spermatozoa of the teiid lizards *Ameiva ameiva* in an attempt to study variation in sperm structure within Teiidae. Epididymal mature spermatozoa were obtained from an adult individual collected in Goiás State, Brazil, and examined with transmission electron and light microscopes. Some of the features described are: a depressed acrosome anteriorly, paracrystalline subacrosomal material with radial organization in transverse section, larger nuclear rostrum, and columnar mitochondria with linear cristae. The authors found that *A. ameiva* shared several character states with the teiid *Cnemidophorus sexlineatus* and the gymnophthalmid *Micrablepharus maximiliani*. Nonetheless, there are high levels of polymorphism in spermatozoa structure between the two teiids. Although no synapomorphies of Teiidae or Teiioidea (Gymnophthalmidae + Teiidae) were identified, four unique features of sperm ultrastructure in *A. ameiva* were found.

GIUGLIANO, L. G., R. D. TEIXEIRA, G. R. COLLI, AND S. N. BÃO. 2002. Ultrastructure of spermatozoa of the lizard *Ameiva ameiva*, with considerations on polymorphism within the family Teiidae (Squamata). Journal of Morphology 253:264–271.

How Reed Frogs (*Hyperolius nitidulus*) Detect Fire

Mechanisms of fire detection have been developed by several organisms living in fire-prone habitats, such as the West African savannah. Based on field observations in Ivory Coast, the authors hypothesized that aestivating juveniles *Hyperolius nitidulus* can hear the sound of fire and respond by fleeing into a nearby safe habitat. To test this hypothesis, the authors conducted playback experiments at Comoé National Park, Ivory Coast, in January 2001. Using amplified speakers, the sound of fire and other control sounds were played next to several specimens of *H. nitidulus*. The majority of frogs reacted strongly to the sound of fire by raising their heads, scanning their surroundings, and fleeing into nearby vegetation. Control noise stimuli were ignored. Nonetheless, frogs

did not respond to playbacks of fire in February–March, which according to the authors indicates the existence of a time-window in which frogs respond. This is the first experimental evidence that anurans use airborne sounds not just for intraspecific communication.

Frog Melanophores as Drug Detectors

Melanophores are an important class of chromatophores that contain dark brown melanin pigment granules. In response to appropriate stimuli, melanophores can appear dark if the pigment granules undergo dispersion throughout the cells, or light if the granules aggregate in the center of the cells. This response is mediated by heptahelical receptors or G-protein coupled receptors. The authors transfected melanophores of *Xenopus laevis* with the human opioid receptor 3 and tested them as biosensors for detection of two opioids—morphine and DAMGO. Absorbance readings in an aggregation assay showed that both substances caused aggregation of pigment granules in melanophores (i.e., cells become lighter). These melanophore biosensors have potential use for detection and measurements of substances in body fluids such as saliva, blood plasma, and urine.

Herpetology at the Yale Peabody Museum of Natural History

GREGORY J. WATKINS-COLWELL
Yale Peabody Museum, Department of Vertebrate Zoology
170 Whitney Avenue, P.O. Box 208118
New Haven, Connecticut 06520-8118, USA
e-mail: Gregory.Watkins-Colwell@yale.edu

Systematic collecting at Yale began in 1802 with the appointment of Benjamin Silliman, who acquired a large mineral collection for teaching purposes. This teaching collection became famous and helped attract many undergraduates to Yale, including Othniel Charles Marsh (Fig. 1), whose education was funded by his uncle, George Peabody. In 1866, near the end of Mr. Peabody's life, he donated funds to the University for the construction of a Natural History Museum (Fig. 2). In the same year, Marsh was appointed as the first Professor of Paleontology in the U.S. (second in the world). The Yale Peabody Museum opened to the public in 1876. Though the original museum had no formal herpetology collection, it did have a vertebrate paleontology collection and a collection of representative vertebrate osteology specimens for comparative use. Addison Emery Verrill (Fig. 3) was named the first Curator of Zoology in 1866. Although his primary interest was invertebrate zoology, he did collect specimens and described species in almost every major group of animals. Over time, the zoology collections grew and expanded into wet collections and study skins, in addition to osteological specimens. Ultimately the Division of Zoology was divided into the divisions of Invertebrate Zoology, Entomology and Vertebrate Zoology, with subdivisions of the latter into Ichthyology, Ornithology, Mammalogy and Herpetology.

FIG. 1. Othniel Charles Marsh (1831–1899), the founder of the Yale Peabody Museum of Natural History. Courtesy of the Peabody Museum of Natural History, Yale University.

History.—The oldest cataloged reptile in the collection is a *Phrynosoma cornutum* (YPM 00625) collected in Texas during June 1860 by "A. C." (no other data available on the collector). The oldest amphibian was collected 21 September 1861 and is a *Rana sylvatica* (YPM 03145) collected in Westville, Connecticut by Henry Shaler Williams. Williams contributed specimens to nearly every collection at the museum and was named Silliman Professor of Geology in 1894. He also was a founder of the national organization of Sigma Xi.

FIG. 2. The Peabody Museum of Natural History entrance off Whitney Avenue. Copyright © Peabody Museum of Natural History, Yale University.

The earliest specimens in the collection include those collected by Addison Emery Verrill from the island of Dominica in the late 1890's. The early part of the 20th century saw a few additions to the collection through collecting expeditions sponsored by the museum. North American collections were enhanced significantly by the work of Marshall B. Bishop and Stanley C. Ball, both of whom contributed significant collections from Florida, Connecticut, and Africa. In fact, the *Scaphiopus holbrookii* specimens collected in Connecticut by Ball during preparation of his monograph on the species represent populations that are now thought to be extirpated (Klemens 1993). In the 1950s, Willard D. Hartman collected caecilians from the Seychelles and also several important specimens from India and Papua New Guinea. However, until the 1960s herpetology held no official status in the museum.

FIG. 3. Addison Emery Verrill (1839–1926) collected many of the earlier Caribbean specimens and was the first Curator of Zoology at the museum. Courtesy of the Peabody Museum of Natural History, Yale University.

The Division of Vertebrate Zoology was officially formed in the 1950s. Thomas Uzzell Jr. was appointed the first Assistant Curator of Herpetology in 1967. His work focused on sexuality and evolutionary biology of salamanders and lizards. Under his guidance, the herpetology collection grew during the late 1960s and 1970's. It was also under his guidance that the collection was completely re-cataloged, utilizing new tag series.

After Uzzell left in 1972, herpetological leadership was largely filled by other staff within the Vertebrate Zoology division, including Curatorial Affiliates. During the mid-1970s and 1980s some specimen collection continued, though not on any large scale.

Computerization of the collection catalogues at Yale Peabody Museum of Natural History began in 1991 under the supervision of Lawrence Gall. The collections of the Vertebrate Zoology Division were among the first to be completely entered into the computer database. In 1993 the collections became searchable via the Internet, which continues today to be a valuable resource for searching the collections.

In 1995, Jacques A. Gauthier joined the museum staff as Curator of Vertebrate Paleontology and Acting Curator of Vertebrate Zoology. The collections began to grow, especially in terms of osteological specimens. Additionally, field expeditions were again organized including trips to Kenya and China led by James D. Lazell, and recently a joint venture with University of Kansas Natural History Museum and Biodiversity Research Center to El Salvador.

In June 1999, Gregory J. Watkins-Colwell joined the staff as a Curatorial Affiliate (a five-year appointment). David Skelly was named Assistant Curator in early 2000. In June 2001, Watkins-Colwell became Museum Assistant for Vertebrate Zoology with primary responsibilities being within herpetology and ichthyology. Currently the Curatorial Affiliates within Herpetology, in addition to Watkins-Colwell, are Theodora Pinou, James D. Lazell, and George D. Whitney.

Collections.—The herpetological collections at the Yale Peabody Museum of Natural History vary widely in geographic and taxonomic coverage (Table 1). In general, most of the approximately 19,000 specimens in the collection are North American in origin (46% of herpetological collection) with the majority of those being from Connecticut, Florida and Texas (15%, 14.7%, and 5% of all herpetological specimens respectively). The majority of non-United States localities are from Africa (29%). Among African sites, Egypt is the most represented with 2497 specimens collected by C. Maser, among others, in the early 1960s, including a large series numbering more than 1000 *Chalcides ocellatus*. Cameroon and Dahomey (now Benin) are also well represented by 935 (5.5% of the herpetological collection) cataloged specimens collected by Charles D. Miller in the 1970s, with roughly twice this number remaining to be cataloged. Asia accounts for 9% of the collection, with most of those specimens coming from China and Hong Kong (796 specimens collected by expeditions of J. D. Lazell, 1997–present). Caribbean specimens represent 8% of the collection, with the largest portion of them being from Haiti.

Throughout his time working with the collection, Verrill added 132 specimens; mostly from the U.S. (especially Connecticut), but also from Dominica and Venezuela. These specimens include an adult *Iguana delicatissima* collected in 1906 from Dominica. Twenty specimens in the collection were obtained by O. C. Marsh, mostly from Wyoming and Texas. Additionally, G. Baur contributed 15 specimens, mostly turtle skeletons.

The collection also includes specimens from some well-known collectors. Many of the specimens were undoubtedly received via exchange. One specimen of *Heloderma horridum* (YPM 10618; skeleton) was collected from Colima State, Mexico by J. Xantus. Raymond Ditmars collected a *Clemmys muhlenbergii* (YPM 10709; skeleton; received as a gift from Dr. R. W. Shufeldt of Washington, DC in the 1930s) from New York. A single *Alligator mississippiensis* (YPM 6528) was collected by Pope (presumably

TABLE 1. Approximate percentages of the total herpetological collection collected from each geographic region. Percentages are rounded to the next highest whole number. Total number of specimens is approximately 19,000.

Geographic Area	Approximate Percentage of Total Collection
North America	46%
Africa	29%
Asia	9%
Caribbean	8%
Europe	2%
South America	2%
Central America	2%
Australia	1%
Unknown Locality	1%

Clifford) in Miami, Florida and received by the museum in 1931. Thomas Barbour collected a *Cyclura cornuta* (YPM 10729; skeleton) which was received as a gift from him in 1934. A mounted skeleton of *Sphenodon punctatus* (YPM 723) was collected by J. Haast. Two specimens of *Chirindia rondoensis* (YPM 6916 and 6917) were collected by C. J. Ionides from Tanzania. Lorenz Müller collected some 50 specimens, mostly from Germany and Yugoslavia.

The collection includes 101 type specimens representing nine taxa. Taxa represented by type specimens are *Amphisbaena gonavensis* (YPM 3384 holotype, YPM 3386–3389 paratypes, YPM 3385 allotype), *Anolis whitemani* (YPM 3641 paratype), *Cophixalus pipilans* (YPM 5281–5283 paratypes), *Eleutherodactylus leoncei* (YPM 1167 holotype; YPM 1188–1201 paratypes), *Eleutherodactylus furcyensis* (YPM 670–679 paratypes), *Eleutherodactylus heminota* (YPM 704–760 paratypes), *Nyctimystes trachydermis* (YPM 5435–5436 paratypes), *Opipeuter xestus* (YPM 6575, 6576 paratypes), and *Typhlops gonavensis* (YPM 3003 holotype; YPM 3004 paratype, exchanged to MCZ).

Recent Improvements.—On 26 October 2001 the Environmental Science Center was dedicated on the Yale campus. This three-story 100,000 square-foot building will serve as a center for museum-based research. In addition to housing research laboratories and lecture rooms for courses in biodiversity and related fields, the multi-million dollar building also houses the museum's collections in Vertebrate Zoology, Invertebrate Zoology, Invertebrate Paleontology, Paleobotany, Botany, and Entomology. Sixty percent of the building is occupied by collections, collection staff, and associated laboratories. Specimens will be maintained in state-of-the-art, environmentally controlled rooms with multiple security measures in place and anti-pest protocols established.

With the opening of new lab and collection space, the herpetology staff is again planning research projects and collecting expeditions. The Division is also working with various state agencies on long-term projects. The specimens resulting from the Maine Amphibian and Reptile Atlas Project, and cited in Hunter et al. (1999) have recently been deposited in the collection. Additionally, all specimens resulting from the 15-year Connecticut Amphibian Monitoring Project will be deposited at the Peabody Museum. Other future projects include faunal surveys of more exotic localities, and increased sampling (including genetic) of lesser-known localities within New England.

ZOO VIEW

Louis A. (Trooper) Walsh III retired last year from his position as Biologist/Museum Specialist in the Department of Herpetology, National Zoological Park (NZP), Smithsonian Institution, in Washington, DC. Trooper developed and guided captive management and research projects for Komodo dragons and other reptiles at NZP, and at other institutions internationally, publishing many professional and popular papers on his work. Trooper pioneered and developed behavioral research and breeding techniques for many species of boas and pythons in the early 1970s. Areas of special interest and continued research include maternal egg incubation in pythons and the energetics of reptile eggs in general during artificial incubation. He described differences between the husbandry techniques and environmental cycling employed for the successful breeding of green tree pythons, emerald tree boas, and Brazilian rainbow boas. In addition, he helped develop educational exhibits and programs for animals in the collection at NZP and elsewhere.

Trooper was involved in fundraising for the Komodo Dragon Conservation Fund, an account administered by the Zoo to support conservation projects in the field and captivity. As a pivotal member for the Komodo dragon working group under the auspices of the American Zoo and Aquarium Association (AZA) and project coordinator for the NZP Komodo dragon breeding program which resulted in the first successful reproduction outside of Indonesia, he has been directly involved in husbandry and research for these lizards. Trooper has published on the thermal biology of captive and free ranging wild dragons. He prepared the Komodo Dragon Taxon Management Account (TMA) and Egg Growth Data compilation published in the Proceedings of the December 5–7, 1995 Komodo Dragon World Conservation Union (IUCN) Workshop in Bogor, Indonesia. The next year, his TMA was published by the AZA. With other workers at the Zoo and in the academic community, he described anesthetic techniques, sonomorphological sex determination in subadults, husbandry and breeding observations, oxygen uptake by eggs as well as energetics of prolonged development in this reptile.

Beginning in 1996, Trooper and Colomba de La Panouse, Zoological Director at Parc Zoologique et Botanique de Thoiry began developing an international conference, to be hosted by Thoiry, on the advances in captive and wild management of dragons. Many varanid biologists were invited to attend the Thoiry International Komodo Dragon Conference, 4–7 November 1998. Their presentations stimulated a high level of enthusiasm and dynamic interchange which subsequently led to a book "Komodo Dragons. Biology and Conservation," based in part on the papers presented in Thoiry. Trooper and Colomba are co-editors (with Claudio Ciofi and me) of this book, recently published by Smithsonian Institution Press. One of the chapters reflects a play behavior study with a large female dragon named "Kraken" at NZP as she interacted with inanimate objects and humans. As I watched Trooper interact with Kraken during some of the trials, I was so deeply impressed by his rapport with her; it was fascinating to witness!

Trooper is one of the best animal caretakers I have ever known. Be it dragon or python, his understanding of their behavior and needs in captivity is quite exceptional. All of his first hand knowledge will not be lost to the herpetological community, however, for he has just formed a consulting company called "ZooGenesis" to advise clients about potential research projects, exhibition and captive maintenance for amphibians and reptiles.

Two of my zoo colleagues, Kevin M. Wright, Director of Living Collections at the Phoenix Zoo, and Brent R. Whitaker, Director of Animal Health at the National Aquarium in Baltimore, have published a seminal book, "Amphibian Medicine and Captive Husbandry," which is an essential reference for veterinarians and any practitioner involved in maintaining a captive colony of amphibians. This terrific compilation, with 27 chapters by top specialists, is certainly the definitive source for the diagnosis and treatment of diseases. Moreover, there is plenty of

information about husbandry including environmental parameters, diet and nutrition.

Kevin and Brent are certainly qualified to oversee a project of this magnitude. Kevin was Curator and Veterinarian of Amphibians and Reptiles from 1993 to 1999 at the Philadelphia Zoo and is an adjunct professor of Clinical Sciences at the University of Pennsylvania School of Veterinary Medicine. Brent oversees the medical management of the amphibian collection at the National Aquarium, probably the largest assemblage of Neotropical hylids and dendrobatids in any zoo or aquarium. The book is available from Krieger Publishing Company.

Over the past several decades, there has been a dramatic increase in the number of publications on various herpetological subjects in Australia. In concert with this increased activity, zoo workers have expanded their research and conservation projects as well. Chris Banks has been a leader in this resurgence which is obvious when his contribution on the history of herpetology at his zoo is read in its entirety.

A Thirty-Year History of Melbourne Zoo's Herp Department

CHRIS BANKS
Melbourne Zoo, PO Box 74
Parkville, Victoria 3052, Australia
e-mail: cbanks@zoo.org.au

Melbourne Zoo has displayed reptiles for many years—extracts from Board Reports note the death of a Boa Constrictor in 1878 and the then Reptile House being destroyed by fire in May 1882 (de Courcy 1995). In the mid-1960s, the Zoo embarked on a new Masterplan, involving the development of more naturalistic exhibits. Among the new developments was a Reptile House, although the decision was taken to implement this via conversion of a large, unused storage building.

This building had started life as a large wire aviary, which was constructed in the 1930s. It was gutted in early 1968 and construction of the exhibits and internal holding areas occurred over the following year (Fig. 1). Key features underpinning the effectiveness of the exhibits are the clear roof panels, which allow natural light through for the live plants, and the front servicing of the displays. The latter aspect allows large branches, etc. to be positioned in the exhibits and for the staff, whilst landscaping, to view the exhibit as it is by visitors.

FIG. 1. The front of the Reptile House as it appeared when the building was reopened, as the Reptile House, in October 1969.

FIG. 2. The central holding area, as it was in the early 1970s.

CAPTIVE BREEDING

The first four years were relatively quiet, with the first breeding in the new building occurring in 1970–Common Iguana (*Iguana iguana*) and Banded Basilisk (*Basiliscus vittatus*) among the four species bred in that year (Banks 1984). Notable successes since include the first Elongate Tortoise (*Indotestudo elongata*) hatches in Australia in 1974; Freshwater Crocodiles (*Crocodylus johnstoni*) in 1975 (world first captive breeding) (Dunn 1977); Thorny Devils (*Moloch horridus*) (wild-mated female) in 1976 (Dunn 1978); Saltwater Crocodiles (*Crocodylus porosus*) in 1979 (Dunn 1981); Arafuran File Snakes (*Acrochordus arafurae*) in 1983 (world first captive breeding) (Dunn et al. 1987); D'Albert's Pythons (*Liasis albertisii*) in 1985 (Banks 1985); Twist-neck Turtles (*Platemys platycephala*); Reticulated Gila Monster (*Heloderma s. suspectum*) in 1998; Fijian Banded Iguana (*Brachylophus fasciatus*) in 1996; Striped Legless Lizard (*Delma impar*) (world first captive breeding) in 1998 (Banks et al. 1999); and Rhinoceros Viper (*Bitis nasicornis*) in 1997.

Since the current House was opened in October 1969, 88 species of reptiles and amphibians have been bred—13 species of amphibians in two orders and five families, and 75 reptiles from three orders and 17 families.

UPGRADING HOLDING FACILITIES

The current House presents animals in a range of naturalistic exhibits that utilize living plants and attempt to recreate the habitats of the species displayed. However, it was not designed to house and display reptiles and amphibians, and significant problems became apparent soon after opening. Foremost amongst these was an inability to appropriately control air temperatures in the off-limit holding areas, due to lack of insulation. Apart from creating difficulties for the keepers in maintaining appropriate conditions for the animals, this system was wasteful of energy and a poor working environment for the staff. An oil-fired burner—the main heat source for the exhibits—was located in the center of the main off-limit holding area. This unit was not reliable and periodically released smoke and fumes, adding to keeper frustrations.

A second issue, which became apparent through the gradual change in working practices in zoos since the mid-1980s, was the need to upgrade the holding environments for the animals. At opening, enclosures in the service areas were arranged at one level on shelves and benches. The enclosures themselves comprised a range of wooden boxes and glass aquaria of differing sizes. Heating was delivered by suspended infra-red heat lamps (Fig. 2).

A three-pronged program to address these issues was commenced in 1987:

1. Conversion of the off-limit holding enclosures to tiered holding units (Fig. 3).
2. Conversion of the heating source from oil to natural gas and relocation of the heating units outside the building.
3. Installation of insulation in the ceiling areas and compartmentalization of the different off-limit areas.

Regional Management

The Australasian Regional Association of Zoological Parks & Aquaria, Inc. (ARAZPA) was established in 1967 (Mumaw 1992), based on the desire to maximize the value of the animal collections in its zoos, particularly their role in wildlife conservation. Like other regions, ARAZPA has a number of Taxon Advisory Groups, or TAGs, and the Reptile & Amphibian TAG was established in April 1990, with Melbourne Zoo's Curator of Herpetofauna filling the position of Reptile TAG Convenor (Banks 1999a). This involvement has continued and expanded over subsequent years and Herp Section staff fill a number of TAG positions and manage 12 taxa for the region.

The Jump into Frogs

Despite the fact that most people like frogs and these are marvelous animals for talking about concepts such as development, communication, and diversity of reproductive modes, frogs, and amphibians generally, are traditionally a sadly neglected group in zoo displays (Maruska 1986; Peterson 1996). A desire to address this failing, together with increasing awareness of global declines (Barinaga 1990), were the stimuli that finally resulted in a dedicated frog display at Melbourne Zoo in 1992. This also caused the Section to change its name from "Reptiles" to "Herpetofauna" to reflect its breadth of activities more accurately.

Designed completely in-house and with major funding support

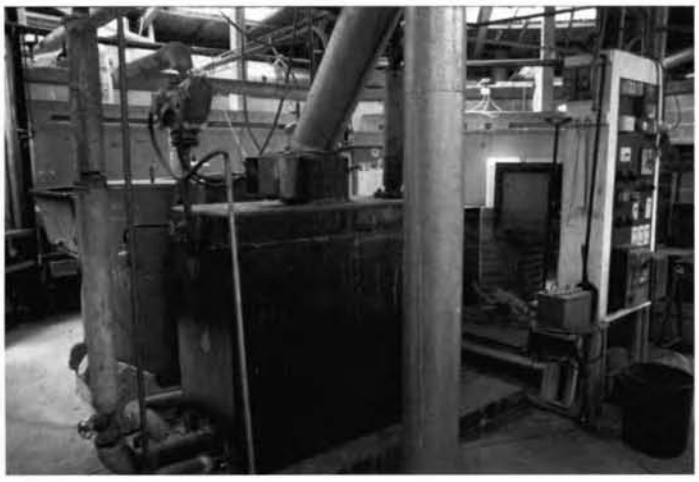

Fig. 3. The new tiered holding boxes, 1999.

Fig. 4. One of the larger exhibits in the "World of Frogs," opened in 1993.

from the Confectionary Division of Cadbury Schweppes Pty. Ltd, the Zoo's "World of Frogs" complex was officially opened on 18 August 1993 (Banks 1995). This comprised eight naturally landscaped exhibits of varying sizes, two off-limit research and breeding rooms, and an external wetland habitat (Fig. 4). Up to 12 species of amphibians are displayed at any one time and a large glass window allows viewing into the breeding rooms. Each exhibit has its own lighting, heating, misting, and biofiltration system.

Although this facility has provided the main visitor focus for the Section's amphibian endeavors, the range of involvements has been much broader, e.g.:

- An *ex situ* conservation program for Romer's Tree Frog, *Philautus romeri*, in Hong Kong (Banks 1996).
- Successful breeding of 12 species.
- Regular participation in Frog Week activities and field surveys.
- Ongoing links with the Amphibian Research Centre (ARC) and other researchers studying the chytrid fungus.
- Training of staff from other zoos in amphibian husbandry and breeding techniques, and enclosure design.

A Move into Conservation

Melbourne Zoo Herp Section's direct involvement in conservation programs, particularly *in situ*, really began in 1990 and has since focused on six main species or groups:

1. Striped Legless Lizard, *Delma impar*.

The Striped Legless Lizard, *D. impar*, is listed as Vulnerable at both national and global levels, and as Endangered in Victoria (IUCN 1996; Stanger et al. 1998). It is restricted to patches of native temperate grasslands across southern Victoria and in the ACT. Its management is coordinated by a National Recovery Team and, in Victoria, by the Victorian Striped Legless Lizard Working Group (Banks 1992). Melbourne Zoo plays a key role in the Working Group, especially through provision of the Convenor and meeting venue, but it also acts as the location for receipt of all specimens rescued through salvage operations in Victoria (Kutt et al. 1995). Zoo staff also support field work and salvage operations, and the first captive breeding occurred at the Zoo in 1998 (Banks et al. 1999).

2. Native Australian frogs.

The Action Plan for Australian Frogs lists 27 species as Vulnerable or Endangered and another 14 species that are of "potential concern" (Tyler 1996). Melbourne Zoo's Herp Section has supported Action Plan goals since 1991, including through:

- Captive management and rearing of *Geocrinia rosea* at the request of Western Australian agencies, in support of the threatened *G. alba* and *G. vitellina* (Birkett et al. 1999).
- Captive management of *Taudactylus acutirostris* at the request of the Queensland & Northern NSW Threatened Frog Recovery Team (Banks and McCracken, *in press*).
- Developing captive protocols for the Stuttering Frog, *Mixophyes balbus*, with NSW agencies.

3. Romer's Tree Frog, *Philautus romeri*.

Romer's Tree Frog, *P. romeri*, is a small rhacophorid restricted to a handful of Hong Kong islands. The development of the new international airport threatened to destroy one third of the frog's breeding sites and assistance was sought with establishing off-shore colonies and locating potential re-release sites (Banks 1996). Melbourne Zoo subsequently salvaged 30 frogs from the main island, Chek Lap Kok, and established a successful breeding program in the Reptile House. Over 800 captive-bred frogs were later returned to Hong Kong for release into new field sites identified by Hong Kong researchers. These releases, plus those of frogs and tadpoles bred at the University of Hong Kong, have all been successful and continue to be monitored by local scientists and volunteers (Dudgeon and Lau 1999).

4. Philippine Crocodile, *Crocodylus mindorensis*.

The Philippine Crocodile, *C. mindorensis*, is the most threatened species of crocodile in the world, with probably no more than 100 adults remaining in the wild (Ross 1998). Melbourne Zoo first became involved with the species in 1992, through links with Silliman University on Negros Island. A tripartite Memorandum of Agreement was signed in January 1993, between the Zoo, Silliman University, and the Philippine Department of Environment & Natural Resources (DENR). This provided the framework for directing funding and logistic support to Silliman University's breeding group, funding of a community awareness poster distributed throughout the Philippines, and for importing crocodiles into Melbourne Zoo. Over the next few years, links were established with other centers in the Philippines, particularly the Crocodile Farming Institute on Palawan Island, and interested groups in the United States and elsewhere in Australia (Banks 1996b). Since 1996 the Zoo has focused on writing the National Recovery Plan (Banks 2000) and supporting protection of a wild population in the Northern Sierra Madre region.

5. Philippine amphibians.

Like all faunal groups in the Philippines, amphibians are under great threat from habitat loss and ongoing degradation. In order to arrive at a better understanding of the status of Philippine amphibians, the Zoo's Herp Curator convened and chaired a meeting of Philippine herpetologists on Palawan in April 1999. This resulted in an additional 30 species being recommended to the IUCN and the Protected Areas & Wildlife Bureau (PAWB, Philippines) for inclusion on threatened fauna lists (Banks 1999b). The April workshop highlighted low community awareness of frogs in the Philippines, which was followed up with a schools and community-based project in the Los Banos area on Luzon Island. The Zoo helped to fund the project and is providing editorial and technical advice.

6. Southeast Asian tortoises & freshwater turtles.

Melbourne Zoo developed a support program in 1998 to help address the Asian Turtle Crisis and launched a public campaign in December 2000. The latter has since generated over A.$11,000, which has funded two staff and veterinary supplies at the Turtle Conservation & Ecology Project in Cuc Phuong National Park, Vietnam, an information brochure on Vietnamese turtles (in Vietnamese), and a CITES manual in Chinese.

The Future

Melbourne Zoo Herp Section's operations and involvements have changed dramatically over the last 30 years and there is no reason to suggest that the next 30 years will see any decrease in this, as zoos themselves continue to evolve. Zoos have demonstrated that they have a range of roles in helping to conserve the natural biodiversity of this planet, which is surely the greatest challenge facing us all.

Acknowledgments.—Apart from his landscaping and artistic skills, Roy Dunn led the Section as Curator from 1969 to 1975. Many keepers, both past and present, have contributed to the success of the Section over the past 30 years.

Scavenging Behaviors of Cottonmouth Snakes at Island Bird Rookeries

* *To whom correspondence should be addressed*

Cottonmouth snakes, *Agkistrodon piscivorus*, are well known as generalist and opportunistic feeders consuming fish, amphibians, rodents, birds, various reptiles including snakes and conspecifics, and carrion (Gloyd and Conant 1990; Savitzky 1992). The Florida cottonmouth, *A. p. conanti*, is an abundant snake throughout much of Florida, with well-established populations on some of the offshore islands. The success of this species in varied habitats is related, in part, to the wide range of prey items that provide a potential energy base for populations (see also Fritts 1988).

Insular populations of cottonmouths inhabiting the Cedar Keys of Florida have been studied by Wharton (1966, 1969) who focused his investigations on an unusually dense population of snakes inhabiting Seahorse Key. This island is approximately 64 ha in size and was estimated to support 600 cottonmouths during the period when Wharton conducted his studies. The island has no permanent fresh water, and the cottonmouths inhabit a mixed hardwood forest where they are entirely terrestrial. These snakes subsist largely or entirely on fish that are dropped or regurgitated by colonial wading birds that nest on the island in large numbers from March through September or October. At present, the colonial nesting birds are largely represented by Brown Pelicans (*Pelecanus occidentalis*), Double-crested Cormorants (*Phalacrocorax auritus*), White Ibis (*Eudocimus albus*), and several species of herons and egrets.

One of us (HL) has confirmed and extended the observations of cottonmouth behaviors recorded by Wharton. At Seahorse Key these snakes characteristically forage at night on substrate directly beneath bird rookeries where avian excreta alter the vegetation and humus layers of soil. Foraging snakes methodically investigate these environments where numerous objects become splattered with fluids that are regurgitated or excreted by birds and presumably contain fish odors. The snakes largely consume fish, although occasional young birds fallen from nests might also be ingested. It is not clear, however, whether birds are eaten for their own sake or because they bear fish odors. Dead birds that are ignored by snakes are frequently found in or near the rookeries. Both their shape and size seem to render them too difficult to swallow. Foraging snakes are generally quite placid and can be approached and observed at close distances. They readily eat fish when these are presented to, or thrown near, a foraging snake. Snakes are also observed to investigate and grasp objects such as plant materials, bones, or bird feathers that have contacted avian excreta or fish fluids. These are usually released following contact with the internal tissues of the mouth.

Recently we observed some unusual scavenging behaviors in a foraging female cottonmouth estimated to be about 110 cm in total body length. The snake was first seen at 1810 h EDST and was observed for 20 min while it foraged in an open area beneath a Brown Pelican rookery at Seahorse Key, 2 June 2001. The substrate consisted of sandy soil covered with many fallen twigs, dried leaves, and other scattered debris. Most of these objects were white or mottled because of urates that were excreted by the pelicans nesting overhead. The area was in full sun, and the ambient temperature and humidity at the time of observation were 31.4°C and 61%, respectively. The snake seemed to be in good health and was somewhat distended posteriorad, suggesting possible pregnancy.

The snake crawled very slowly and deliberately over the substrate while investigating various objects with frequent tongue flicks. We first observed the animal through binoculars from a distance of about 8 m. Eventually, we advanced closer to the snake, which continued to forage and eventually approached us within 0.5 m distance. Although the snake seemed to be aware of our presence at this point, it continued to forage as described.

Soon after we first saw the snake, it investigated the ground intensely at one location and positioned its head nearly vertically with the mouth directed downward as it grasped a dark object. When the snake lifted its head, the grasped item was seen to be soil as half of it broke away from that being held in the mouth and

FIG. 1. A female Florida cottonmouth, *Agkistrodon piscivorus conanti*, ingesting a dry mass of fish skull with adhering bones, dry leaves, sticks, and soil debris at a pelican rookery on Seahorse Key. Note the generally white appearance of the ground and numerous white spots on the leaves and other objects, including the snake. These are dried urates excreted by pelicans from the overhead tree canopy.

fell to the ground. The snake then lifted its head upward at an angle of about 30° and swallowed the soil, which was seen to be damp and loosely held together with moisture. Later inspection of the ground on which the snake foraged revealed several locations where the soil was wetted, because of excreta or regurgitated fluids from birds overhead.

Following this act, the snake continued to investigate objects that were on the ground. Next it investigated the blunt end of a wooden branch about 1 cm in diameter and bearing several stains of bird excreta. The snake grasped this branch and attempted to advance the jaws over it, but the object was soon dropped and the effort abandoned. The snake continued to crawl slowly over the substrate using rectilinear locomotion while investigating objects with searching movements of the head and tongue.

Finally, the snake stopped to investigate an object roughly 4 x 4 x 1.5 cm in overall size, composed of a partial fish skull with other bones, debris and several dry leaves adhering to it. The snake grasped this object and advanced its jaws to hold the bulk of the item firmly within its mouth (Fig. 1). Then it elevated its head further off the ground, crawled forward about 3 m and stopped with the head elevated. We believe the item would have been swallowed, but we disturbed the snake while advancing to take photographs. The snake crawled forward and disappeared within the forest edge that bordered the rookery site.

These and other observations of cottonmouth foraging behaviors at Seahorse Key suggest that numerous, diverse objects of appropriate size, shape, and odor might be ingested by foraging snakes. Thus, feces that are defecated by wild-caught snakes sometimes contain leaves that are ingested inadvertently as adhering parts of carrion. In general, *Agkistrodon* species seem to rely more on chemosensory information during foraging than do other crotalines (Chiszar et al. 1979; Cock Buning et al. 1981). It has been suggested that evolutionary reliance on an envenomation feeding system and use of a strongly proteolytic venom, coupled with predominance of chemosensory information during foraging, have likely conferred a predilection for carrion in the cottonmouth (Savitzky 1992). However, the significance of such behavior in energetic contexts has not previously been emphasized.

At Seahorse Key, fish dropped by nesting birds can be a "boom or bust" situation. In the 1970s, as many as 200,000 colonial birds occupied the Cedar Keys, and 95% of all nesting occurred on Seahorse Key (U.S. Fish & Wildlife Service, unpublished records). Such numbers produce abundant and concentrated energy resources for cottonmouths, which literally gorge themselves during periods lasting from April/May to October/November (late fall nesting attributable to pelicans; HBL, unpublished observations). In recent years, however, drought has severely impacted wetlands on which many of the nesting birds depend for feeding their chicks. Consequently, the number of nesting birds has diminished greatly. Recent counts have been as low as 10,000 or fewer nesting birds. During the severe 2000 drought in Florida (especially at Seahorse Key), avian nesting was greatly curtailed at Seahorse Key, and the snake foraging period was shortened to July–October. Moreover, cottonmouths do not forage during drought, even though dropped fish might be available at the rookeries (unpublished observations). Consequently, foraging success can vary greatly from year to year. It seems reasonable to infer that carrion degraded by age or adherence of indigestible materials might be significant resources when snakes employ foraging behaviors that maximize the intake of available energy. Snakes at Seahorse Key remain beneath or very near the rookeries, and they do not usually move extensive distances unless the locations of food resources change (Wharton 1969). Thus, the scavenging of diverse objects that yield potentially useful energy during foraging might have significant selective advantages in island environments where alternative prey items are scarce or limited. The intensive scavenging behaviors of cottonmouth snakes at Seahorse Key perhaps have become incorporated to be part of an "island syndrome" of behavioral and physiological modifications that have evolved in response to resource limitations on islands (Adler and Levins 1994; McNab 1994; Wikelski and Trillmich 1997).

Acknowledgments.—We owe special thanks to Kenneth Litzenberger of the Lower Suwannee and Cedar Keys National Wildlife Refuge management office for a special use permit to study cottonmouth snakes at Seahorse Key. Logistical support was provided by the University of Florida Seahorse Key Marine Laboratory.

Expulsion of Intraperitoneally-Implanted Radiotransmitters by Australian Pythons

DAVID J. PEARSON
Western Australian Department of Conservation and Land Management
PO Box 51, Wanneroo, Western Australia 6065, Australia

and
RICHARD SHINE
Biological Sciences A08, University of Sydney
New South Wales 2006, Australia
e-mail: rics@bio.usyd.edu.au

The availability of miniature radiotransmitters has revolutionized the study of snake ecology (Fitch 1987; Shine and Bonnet 2000). Most workers rely upon surgical insertion of transmitters into the animal's peritoneal cavity, and methods for the surgical implantation of transmitters are now sophisticated and effective (e.g., Reinert and Cundall 1982). As more workers use these techniques, new complications will undoubtedly appear. In this paper we report a bizarre example of such a complication. Free-ranging carpet pythons (*Morelia spilota*) frequently rid themselves of surgically-implanted transmitters by incorporating the transmitter into the alimentary tract and then expelling it with the feces.

Table 1 summarizes 14 occasions when radio-telemetered pythons appear to have expelled transmitters in this way. The transmitters (Holohil models SI-2T and PD-2T) weighed 4 to 22 g, and constituted 0.7 to 3.3% of the mass of the snake into which they were implanted. The transmitters were inserted under isoflurane anesthesia, via a midventral incision approximately 10% of the snake's snout-vent length anterior to the vent. The entire unit (transmitter plus 19–30 cm antenna) was placed inside the peritoneal cavity, with the body of the transmitter positioned anterior to the antenna. The transmitter was not sutured to a rib. The incision was sutured closed, and the snake released 1–14 days after surgery.

In the course of the study, many telemetered snakes were recaptured for transmitter replacement. In all such cases except those described below, the transmitter had remained in place within the peritoneum, and was surrounded by fibrous tissue. In the cases listed in Table 1, however, attempts to relocate snakes in the field revealed only the transmitter, usually in conjunction with fecal material from the snake. Python feces are very easily distinguished from those of other large predators because the python feces are distinctive in shape, are always associated with uric acid deposits, and detailed examination reveals the presence of python teeth. Large carnivorous mammals (e.g., cats, dogs, foxes) are absent from our Garden Island study area and very rare (because of a prolonged control program) at the Dryandra site. Subsequent recapture of two of these free-ranging pythons that had lost their telemeters confirmed that the snake was in good health, and showed no scarring that would indicate loss of the transmitter through the body wall. Evidence of the route of transmitter expulsion was available for two additional snakes. First, an adult diamond python (*Morelia spilota spilota*; not listed in Table 1) was captured and kept in captivity after several months radio-tracking, prior to surgery to remove the transmitter. Before we could remove it, the snake defecated the transmitter in its cage. Second, we dissected a radio-tracked carpet python (*M. s. imbricata*; again not listed in Table 1) that died in the field after 22 months of radio-tracking. The transmitter in this snake was partially incorporated into the stomach, but the antenna remained attached in the peritoneal cavity. It seemed that fecal impaction might have led to the snake's death.

Data in Table 1 show that cloacal expulsion of transmitters was relatively frequent, although by no means universal (these snakes were 14 of 75 pythons radio-tracked during the study). The snakes that expelled transmitters covered a wide range of body sizes, included both sexes, and carried the transmitters prior to expulsion for periods of 1–24 months. At the Dryandra study site, 3 female and 7 male pythons expelled their transmitters from a total of 48 transmitters implanted. This involved 33 individual pythons, as some females were implanted twice. At the Garden Island study site, 1 female and 3 male pythons expelled their transmitters from a total of 52 transmitters implanted (consisting of 42 individual pythons).

To examine correlates of transmitter expulsion, we conducted a logistic regression on data from all radio-tracked pythons. Although some snakes were fitted with more than one transmitter in succession during our study, each animal appeared only once in the data set to avoid pseudoreplication. The dependent variable was whether or not the transmitter was expelled, and the independent variables were the snake's sex and snout-vent length. We excluded four cases where we had less reliable evidence for expulsion (no feces with transmitters: see Table 1) but inclusion or exclusion of these data did not change any of the conclusions from the analysis. The regression was based on 38 female snakes (3 of which expelled transmitters) and 36 males (7 of which expelled transmitters). Likelihood ratio tests from this regression showed that the probability of expulsion was linked both to the snake's sex ($\chi^2 = 6.75$, 1 df, $P < 0.01$) and its body length ($\chi^2 = 4.90$, 1 df, $P < 0.03$). Males expelled transmitters more frequently than did females (7 of 36, = 19% of males, vs 3 of 38, = 8% of females). The mean snout-vent lengths of snakes that expelled transmitters were larger than those of other snakes, in both sexes (males: 145 vs 119 cm; females, 188 vs 175 cm). There was no significant difference in rates of expulsion between the two study areas.

The most consistent correlate of expulsion involved feeding. Ten of the 14 expulsions were associated with fecal material (Table 1), suggesting that transmitters were expelled soon after the snake had consumed a large prey item. Although many of the other radio-tracked snakes took equally large meals and did not expel transmitters afterwards, we suspect that there is a functional link between feeding on a large meal, and transmitter expulsion. Not only

TABLE 1. Cases in which radio-telemetered carpet pythons (*Morelia spilota imbricata*) expelled intraperitoneally-implanted transmitters. SVL = snout-vent length (cm). The Table shows the characteristics of snakes, the dates at which transmitters were surgically implanted and were later found in the field (without the snake), and whether or not snake feces were present with the relocated transmitter. *For snake 22, the original transmitter was not found, but the snake was recaptured 25 Nov 1998 without its transmitter. Note that snake 80 was also recaptured 14 Nov 1995 and reimplanted after voiding its first transmitter.

was transmitter loss linked to feeding events (Table 1), but the sexes and sizes of snakes that most frequently expelled transmitters (large specimens, and males rather than females) are those that tend to take very large prey (relative to snake size) in our study populations (unpubl. data).

Why should a snake consuming a large meal be likely (or indeed, able) to transfer an object in its peritoneal cavity into its alimentary tract? This ability might be linked to massive temporal shifts in size and activity of the alimentary tract in ambush predators such as pythons (Secor and Diamond 1995), including carpet pythons (Bedford 1996). The gut shrinks during non-feeding periods, but is massively up-regulated soon after a prey item is ingested. It might be able to incorporate foreign objects during this rapid increase in size. This ability might function in removal of objects such as fish spines that can penetrate the stomach wall and lodge in the peritoneum (Shine 1991).

The same ability to expel intraperitoneally-implanted transmitters through the gut has been reported in fishes (Chisholm and Hubert 1985; Marty and Summerfelt 1986), and might prove to be widespread. The only analogous phenomenon in snakes (to our knowledge) involves passive integrated transponder microchips surgically implanted in the necks of corn snakes (*Elaphe guttata*); the tags frequently (and sometimes rapidly) moved posteriorly through the body and were expelled in the feces (Roark and Dorcas 2000). If such abilities are widespread, there is an obvious caveat for interpretation of radiotelemetry studies. Researchers finding a transmitter in the field would be tempted to conclude that the animal carrying that telemeter had died and/or been consumed by a predator. Marks on a transmitter left by teeth or claws of a predator species would be interpreted as evidence for such an event, but may have been inflicted after expulsion of the unit. We advocate caution in inferring predation as a cause of death of radio-tracked snakes, unless the carcass (or part of it) is available.

Studies on fishes have attempted to determine whether changes in factors such as the size or coating of a transmitter can reduce the probability of expulsion. Smaller transmitters were less likely to be expelled (Marty and Summerfield 1986), but the transmitters used in our own study were smaller relative to snake body mass (< 4%) than is the case in most such studies. Anchoring the transmitter by suturing it to a rib during the initial surgery or by running the antenna subcutaneously (e.g., Reinert and Cundall 1982; Reinert 1992) is one obvious solution, but experimental work on fishes found that anchoring the transmitters greatly increased the rate at which they were expelled via rupturing the animal's body wall (Marty and Summerfield 1986).

Our results are interesting not only in providing a cautionary note about interpreting cases of transmitter loss, but also in revealing a hitherto-unsuspected ability of snakes to encapsulate and expel a foreign object from the peritoneum. The apparent link between expulsion and feeding (and especially to ingestion of prey that are very large relative to the predator), in a lineage of snakes known to show massive fluctuations in size and activity of the alimentary tract, strongly suggests the ability to regulate organ size in this way might have more diverse consequences than has hitherto been recognized.

Acknowledgments.—We thank Andy Williams for field assistance, the Australian Department of Defense for access to the Garden Island site, and the Australian Research Council for funding.

Mouthpart Pigmentation in *Rana muscosa* Tadpoles: Seasonal Changes Without Chytridiomycosis

LARA J. RACHOWICZ
Department of Integrative Biology, University of California
Berkeley, California 94720-3140, USA
e-mail: larar@socrates.berkeley.edu

Chytridiomycosis, an amphibian skin disease caused by the fungus *Batrachochytrium dendrobatidis*, has been implicated in amphibian declines in Australia, Europe, North America, and the Neotropics (Berger et al. 1998; Bosch et al. 2001; Daszak et al. 1999; Nichols et al. 2001). At least 93 amphibian species over six continents have been found to be infected with this chytridiomycete (Speare and Berger 2000). *Batrachochytrium* infections have been found in both tadpoles and adults. In postmetamorphic anurans, chytridiomycosis is associated with high mortality, but infections in tadpoles are restricted to the mouthparts and are not associated with mortality (Berger et al. 1998; Pessier et al. 1999).

Batrachychytrium grows on the keratinized epithelial cells of adult amphibians (Longcore et al. 1999) and keratinized mouthparts of some ranid and hylid tadpoles (Fellers et al. 2001; G. Fellers, pers. comm.). The superficial keratinized cells of the upper and lower jaw sheaths and tooth rows of tadpoles are typically heavily pigmented (Luckenbill 1965). Recent attention has been focused on the loss of pigmentation in mouthparts as an indicator of chytridiomycosis (Fellers et al. 2001; Vredenburg and Summers 2001). Fellers et al. (2001) found that conspicuous oral disc abnormalities including depigmented tooth rows, depigmented jaw sheaths, and swollen labial papillae (along the margins of the oral disc) are strongly associated with *Batrachochytrium* infection in the mountain yellow-legged frog, *Rana muscosa*. However, evidence presented here suggests that loss of pigmentation in tadpole mouthparts might not always be associated with chytridiomycosis and that pigmentation might vary seasonally. This paper (1) describes mouthparts and histological results for tadpoles showing abnormalities characteristic of chytridiomycosis; (2) describes seasonal changes in mouthpart pigmentation in tadpoles from several populations; and (3) describes changes in lab-maintained animals that resemble seasonal changes.

Vredenburg and Summers (2001) identified two levels of mouthpart loss in *R. muscosa* tadpoles collected at Ebbetts Pass, Alpine County, California, USA in June 2001: (1) a lack of pigmentation in the tooth rows and only a thin pigmented line on the top and bottom jaw sheaths (Fig. b in Vredenburg and Summers 2001) and (2) a complete lack of pigmentation in the tooth rows and jaw sheaths (Fig. c in Vredenburg and Summers 2001; these figures can also be viewed in color on Amphibia Web at http://elib.cs.berkeley.edu/aw/chytrid/index.html). Large-scale surveys have identified more than 100 *R. muscosa* populations throughout the Sierra Nevada in California that were characterized by a loss of pigmentation in the mouthparts (R. Knapp, L. Rachowicz, V. Vredenburg, unpubl. data). Following Fellers et al. (2001), these tadpoles would be assumed to be infected with *Batrachochytrium*.

Histological evidence suggests that the amount of pigmentation in *R. muscosa* tadpole mouthparts might vary without the presence of *Batrachochytrium*. *Rana muscosa* tadpoles experience one to two winters before metamorphosis and overwinter in ice-covered lakes (Bradford 1983). Fifteen tadpoles from Ebbetts Pass, Alpine County, California, USA were inspected early in the ice-free season (2 June 2001), and all had partially or fully depigmented jaw sheaths and tooth rows (V. Vredenburg, pers. comm.). Two of these tadpoles were collected and photographed (Figs. b and c in Vredenburg and Summers 2001). A survey late in the season (6 September 2001) found that all of the tadpoles surveyed (N = 20) from this same population had fully pigmented jaw sheaths and tooth rows. The population appeared healthy during both surveys (e.g., no die-offs, no emaciated tadpoles, no behavioral changes). The two tadpoles collected from Ebbetts Pass on 2 June 2001 (Figs. b and c in Vredenburg and Summers 2001) and six tadpoles collected from this same location on 6 September 2001 were sectioned and processed routinely for histologic examination, and no *Batrachochytrium* organisms were found.

Field surveys from the 60 Lake Basin, Fresno County, California, USA, also provide evidence for a seasonal trend in mouthpart pigmentation. During the summer of 2001, five populations of *R. muscosa* in the 60 Lake Basin were examined for loss of mouthpart pigmentation on 9 June and then again on 29 July. The June surveys took place approximately one week after winter ice melted. In each survey, 20–26 tadpoles representing two tadpole age classes at each of the five sites were captured, and their jaw sheaths were examined for pigmentation with a 10x hand lens (except at two sites where fewer tadpoles were found). The percentage of tadpoles showing thin or complete loss of pigmentation in their jaw sheaths (resembling Figs. b and c in Vredenburg and Summers 2001) at each site was high in the early season survey and very low in the later season survey (Table 1). All populations seemed healthy during surveys. These populations were not tested for chytridiomycosis.

Laboratory-maintained tadpoles showed variation in mouthpart pigmentation with temperature changes. Ten *R. muscosa* tadpoles representing three age classes were collected on 5 October 2001

TABLE 1. Percent of partially or fully depigmentated jaw sheaths at five lakes surveyed in the 60 Lake Basin, Fresno County, California, USA on 9 June 2001 and 29 July 2001 with the number of *Rana muscosa* tadpoles sampled in parentheses.

Lake	% partially or fully depigmented on 9 June (N)	on 29 July (N)
1	54 (13)	0 (22)
2	100 (21)	0 (6)
3	15 (20)	0 (25)
4	29 (21)	0 (21)
5	75 (20)	8 (26)

from a lake in the 60 Lake Basin. This lake was not in the surveys described above, and the population seemed healthy. Tadpoles were transported to the University of California, Berkeley where they were housed individually in a laboratory at 6°C and fed rabbit chow several times each week (cared for according to approved Office of Laboratory Animal Care standard operating procedures). All tadpoles had darkly pigmented tooth rows and jaw sheaths (similar to Fig. a in Vredenburg and Summers 2001) at the time of capture and on the first day in the lab (7 October 2001). On 28 November 2001, all 10 tadpoles were characterized by depigmented tooth rows and 8 of 10 had partially or completely depigmented jaw sheaths. On 4 December 2001, tadpoles were transferred to a room at 14°C, with all other variables (e.g., light, food ration) remaining the same. After two weeks at this temperature, 8 of 10 tadpoles had fully pigmented tooth rows and 7 of 10 tadpoles had fully pigmented jaw sheaths. On 20 December 2001, boiled spinach was added to the tadpole diet because of a change in standard operating procedures. On 8 January 2002, all tadpoles had fully pigmented tooth rows and 9 of 10 tadpoles had fully pigmented jaw sheaths. Subsequently, one of these tadpole was examined histologically and one examined using a wet-mount preparation of cells scraped from the oral cavity and no evidence of chytridiomycosis was found in either (J. Parker, pers. comm.).

The described observations suggest that *R. muscosa* tadpoles show variation in pigmentation of keratinized cells of the tooth rows and jaw sheaths with changes in temperature. Thus, loss of pigmentation in mouthparts does not always correlate with *Batrachochytrium* infection as confirmed by histology in eight animals from Ebbetts Pass and two lab-maintained animals. In the field, *R. muscosa* tadpoles lacked mouthpart pigmentation early in the season after spending a winter under ice and gained pigmentation as the growing season progressed. Data from lakes in the 60 Lake Basin show temperatures ranging from 2°C to 4°C during the winter and from 8°C to 28°C during the summer (V. Vredenburg, unpubl. data). In the laboratory, tadpoles lost pigmentation at 6°C water temperature and regained pigmentation at 14°C. Although the significance of light pigmentation in jaw sheaths that are typically heavily pigmented is unknown (McDiarmid and Altig 1999), it is possible that the observed changes in pigmented structures are because of the increased feeding associated with warmer temperatures. At high elevations in the Sierra Nevada, tadpoles only feed to a small extent while overwintering (Bradford 1982). At the colder temperature, the laboratory tadpoles were observed to eat approximately half as much as at the warmer temperature. Because structures with melanic pigment have been found to be stronger than those lacking pigment (McDiarmid and Altig 1999), it has been suggested that increased use of mouthparts through feeding might increase the strength of the mouthparts and thus the degree of pigmentation (R. Wassersug, pers. comm.).

Additional surveys need to be carried out, and the infectious status of tadpoles needs to be confirmed in order to understand better the association between chytridiomycosis and pigment loss. It is possible that the association found by Fellers et al. (2001) might not be valid during early summer. It is important to characterize more specifically the erosion of pigmentation in the mouthparts by chytrid infection versus other factors. For example, results obtained from a pilot study suggest there is a particular pattern of pigmentation loss associated with chytridiomycosis, characterized by discrete patches of pigment loss in the jaw sheaths (L. Rachowicz, V. Vredenburg, R. Knapp, and J. Parker, in prep.). Because chytridiomycosis has been found in populations that have undergone declines, it would be prudent for herpetologists to continue to examine tadpole mouthparts and take proper precautions to prevent spreading this disease, as suggested by Fellers et al. (2001) and Vredenburg and Summers (2001) until additional studies are completed.

Acknowledgments.—Funding was provided by the Department of Integrative Biology (UC Berkeley), the Cleveland Zoological Society, and the Canon National Parks Science Scholars Program. I thank Chris Bentis, Lauren Chan, Matt Daugherty, Tate Tunstall, and Vance Vredenburg for field assistance and Roland Knapp, John Parker, Vance Vredenburg, Richard Wassersug, and the Briggs Lab for useful comments.

Absence of Malarial Parasites from Texas Horned Lizards, *Phrynosoma cornutum*

SCOTT E. HENKE
and
ALAN M. FEDYNICH
Caesar Kleberg Wildlife Research Institute
Texas A&M University-Kingsville
Kingsville, Texas 78363, USA
e-mail (SEH): scott.henke@tamuk.edu

The Texas horned lizard (*Phrynosoma cornutum*) population in Texas has experienced a dramatic decline over the past 40 years (Donaldson et al. 1994). Texas horned lizards are thought not to occur in Texas east of an imaginary line from Fort Worth to Corpus Christi and their abundance throughout the rest of Texas is considered to be stable or declining, depending on the region (Donaldson et al. 1994). Consequently, this species is listed as threatened by the state of Texas (Texas Parks and Wildlife Code 1987) and as a Species of Concern by the federal government.

Although there have been several hypotheses as to why Texas horned lizards have experienced such a precipitous decline, including range expansion by fire ants (*Solenopsis invicta*), urban sprawl, grazing and agricultural practices, and pesticide use (Donaldson et al. 1994; Price 1990), little scientific information exists to elucidate the root causes. The situation is complicated by the fact that even though the distribution and abundance of Texas horned lizards have declined throughout most of the state, no single, potentially causative factor occurs statewide. One often overlooked explanation is parasitic diseases. Schall (1982) and Schall et al. (1983) demonstrated that western fence lizards (*Sceloporus occidentalis*) experienced negative physiological and behavioral ramifications, including reduced fecundity, because of the common malarial parasite, *Plasmodium mexicanum*.

Malaria might be a contributing factor in the decline of Texas horned lizards in Texas. Henke (unpubl. data) recently noted that Texas horned lizards in southern Texas had clutches of <12 eggs, which was about half the number of the average clutch considered for the species (Milne and Milne 1950; Sherbrooke 1981). Although a causative link between the decline of Texas horned lizards and malaria cannot be established with circumstantial evidence, these observations do offer an interesting hypothesis about the decline of Texas horned lizards. Only one published study (Thompson and Huff 1944a) examined 58 horned lizards in Texas for malarial parasites; they reported that none were infected. However, their study was conducted in the early 1940's during a period when horned lizards were relatively abundant and not declining in Texas.

Ayala (1970) summarized the extent of the *Plasmodium mexicanum*-like complex found in herpetofauna from western North America, which included two malarial parasite species (*Plasmodium beltrani* and *Plasmodium brumpti*) found in Mexico and a species similar to *P. mexicanum* found in Arizona. Ayala (1973) experimentally infected coast horned lizards (*Phrynosoma coronatum*) and Thompson and Huff (1944b) experimentally infected Texas horned lizards with *P. mexicanum*, demonstrating that this malarial parasite could occur in these hosts as well. The objective of our study was to determine the prevalence, abundance, and intensity of malarial parasites in Texas horned lizards collected throughout Texas.

Texas horned lizards were captured by systematic and random searches, and by road cruising (see Fair and Henke 1997 for description of capture techniques) during May through September 1999 throughout five study regions (i.e., north, west, east, central, and south) of Texas as delineated by Donaldson et al. (1994). Capture locations were selected based on anecdotal evidence that Texas horned lizards were observed on site within the last two years. Horned lizards were measured for snout–vent length (SVL), marked with a passive integrated transponder to identify potential recaptures (Camper and Dixon 1988), and then were released at the site of capture. Lizards were considered adults when SVL ≥ 68 mm (Ballinger 1974). Two thin blood smears from each lizard were made from blood obtained from the caudal vein. Smears were fixed in 100% methanol and stained with Diff-Quick® (Fischer Scientific, Pittsburgh, Pennsylvania). Each blood smear was examined for 30 minutes at 1000x magnification to determine malarial prevalence. This protocol is considered sufficient to detect low intensity infections (Fedynich et al. 1993).

We captured 102 Texas horned lizards during 1999, of which 56 lizards were considered juveniles by our SVL criteria. No protozoan blood parasites, inclusive of *Plasmodium mexicanum*, were seen in any blood sample from Texas horned lizards.

The Texas population of Texas horned lizards does not seem to be affected by malarial parasites. It should be noted that lack of *P. mexicanum* in blood samples is not conclusive evidence of being free from infection. Because Texas horned lizards are a threatened species internal tissue could not be examined for exoerythrocytic schizonts. Possible causes for negative findings include (1) absence of *P. mexicanum* in Texas, (2) absence of appropriate vectors for transmitting *P. mexicanum* to Texas horned lizards, (3) insufficient vector and (or) host densities necessary to maintain infections, (4) infection rates were too low for observing *P. mexicanum* from a sample of 102 host individuals, (5) infections were highly virulent and lethal, which quickly eliminated infected hosts from the population, making detection difficult, and (6) malarial infections were highly aggregated (overdispersed) and our sampling missed these particular host individuals.

Although Texas horned lizards have declined in number throughout most of Texas, there is no evidence from samples of surviving lizards that malaria was a causative factor in the decline. It is possible that the populations of horned lizards we sampled are the survivors of past losses, and at least theoretically, malaria could have been responsible for those losses, but not be present in surviving populations. However, our data suggest that to explain the decline of Texas horned lizards other hypotheses are warranted.

Acknowledgments.—We thank L. Harveson for blood samples from the western region, and B. Ballard, D. Hewitt, W. C. Sherbrooke, and an anonymous reviewer for comments on an earlier draft of the manuscript. Financial support was provided by the Houston Livestock Show and Rodeo Association. Texas horned lizards were captured and handled in accordance with Texas Parks and Wildlife Department (Austin, Texas) Scientific Permit No. SPR-0993-636. This study was approved by the Texas A&M University-Kingsville Animal Care and Use Committee (#1-97-37). This manuscript is Contribution No. 01-115 of the Caesar Kleberg Wildlife Research Institute.

Immature Atlantic Loggerhead Turtles (*Caretta caretta*): Suggested Changes to the Life History Model

W. N. WITZELL
National Marine Fisheries Service, Southeast Fisheries Science Center
75 Virginia Beach Drive, Miami, Florida 33149, USA
e-mail: wayne.witzell@noaa.gov

North Atlantic loggerhead turtle (*Caretta caretta*) populations have extended and complex developmental life histories. Hatchling loggerheads enter the surf and find their way into the pelagic environment where they remain for several years before returning to coastal waters (Musick and Limpus 1997). Carr (1986, 1987) hypothesized that loggerhead hatchlings from the large Florida rookeries become entrained in major current systems (e.g., Gulf Stream) and are passively transported to the eastern Atlantic, and eventually return to the western Atlantic via the North Atlantic gyre. Carr's hypothesis was supported by genetic evidence that immature eastern Atlantic (Azores Islands) loggerheads originated from western Atlantic rookeries (Bolten et al. 1998). These immature turtles are then thought to recruit from pelagic (oceanic) habitats to coastal habitats, migrating north and south along the U.S. east coast sea-

sonally (Musick and Limpus 1997). The Florida turtles mature after several years in coastal habitats and nest at about 92 cm straight carapace length (SCL) (Bjorndal et al. 1983). However, there are pelagic length frequency data and flipper tag recapture data, satellite telemetry and aerial survey data, and historical evidence that suggest the popular conceptual models of loggerhead turtle life histories might be more complicated than previously thought.

FIG. 2. German submarine crew members of U-92 pose with large immature loggerhead turtle under the anti-aircraft cannon near the Azores Islands in December 1942. Photo courtesy G. Sytko.

Carapace length data from stranded turtles along the U.S. Atlantic coast have been used to estimate the size that immature turtles leave the pelagic habitat and enter coastal waters. Stranding data indicate that this settlement size ranged from 25 to 30 cm curved carapace length (CCL) (Musick and Limpus 1997) to 40–60 cm SCL (Carr 1986, 1987; Martin et al. 1989). Bjorndal et al. (2000, 2001) hypothesized from growth data that most eastern Atlantic (Azores Islands) juvenile turtles depart the eastern Atlantic pelagic habitat and recruit to the coastal U.S. habitats between 46 and 53 cm CCL. They also hypothesized that almost all eastern Atlantic loggerheads left the pelagic habitat by 64 cm CCL (presumably to the western Atlantic). Analysis of growth layers in bone sections from stranded turtles has suggested that Atlantic loggerhead turtles might settle out of the pelagic habitat to coastal habitats at 52.0 cm SCL (Snover et al. 2000). An apparent shift in growth layer patterns, termed "settlement lines," theoretically represented the shift from pelagic to coastal habitats. However, dietary analysis suggests that immature loggerhead turtles in the Mediterranean Sea did not permanently settle into coastal waters immediately, but moved back and forth from pelagic to coastal benthic habitats for an undetermined time before settling down (Laurent et al. 1998). Perhaps the extended settlement size range of North Atlantic loggerheads (25–64 cm CCL) lends support to an intermediary developmental phase as hypothesized for the Mediterranean by Laurent et al. (1998).

This flexible shift from strictly pelagic to coastal habitats might also occur in the western Atlantic loggerhead populations. Some immature turtles might stay in the pelagic habitat in the North Atlantic longer than hypothesized, and some turtles might move back and forth between pelagic and coastal foraging habitats. Witzell (1999) reported that the mean (± SD) size of loggerheads caught incidentally by swordfishermen east of the Grand Banks in the north central Atlantic was 55.9 ± 6.5 cm CCL (range = 41–70 cm). Some of these pelagic turtles (11.2%) are close to, or larger than (> 64 cm CCL), the hypothesized settlement sizes when most loggerhead juveniles are assumed to become coastal benthic foragers. The turtles captured near the Grand Banks appear similar to those turtles reported by Bolten et al. (1993) from the Azores (Fig. 1). Bolten at al. (1993, 1994) also encountered some "post-settlement size" (55–80 cm CCL) turtles near the Azores, turtles that were possibly "loafers" or coastal-pelagic "commuters." Some of these turtles are clearly larger than the size range recruiting to coastal benthic habitats, and either stayed in the pelagic habitat, or they returned from the coastal habitat. The turtles that have stayed in the pelagic habitat might be "late bloomers" and are on the verge of settling into coastal habitats. Two turtles tagged aboard swordfish vessels (61.2 cm and 60 cm CCL) on the Grand Banks were recaptured in U.S. coastal waters, and were possibly settling into the coastal habitats (Witzell 1999). One turtle was recovered in North Carolina and the other turtle from west Florida.

There is also evidence that some of these "coastal" and "pelagic" turtles might move long distances and switch between the coastal and pelagic foraging habitats. Large immature loggerheads might make trans-Atlantic movements. A 73.1 cm SCL loggerhead moved from Cape Canaveral, Florida, 5140 km east to the Azores Islands in 18 months (Eckert and Martins 1989). Another turtle (84.0 cm SCL), tagged in the Canary Islands in the eastern Atlantic, moved west 6900 km to Cuba in 5 months (Bolten et al. 1992). Four immature loggerheads (33.9–57.6 cm) satellite tagged at Madeira in the spring moved northwest against the prevailing currents (Dellinger and Freitas 2000). One of these turtles moved over 3000 km northwest to the Grand Banks (45°N, 40°W). Additionally, Morreale (1999) reported two satellite tagged loggerheads that migrated south along the U.S. east coast before moving thousands of kilometers offshore southeast of the Grand Banks. The first turtle (59.1 cm SCL) was tagged in Long Island Sound, New York, in October and moved south to Cape Hatteras before moving northeast in the Gulf Stream a distance of 1800 km. The second turtle (52.2 cm SCL) was also satellite tagged in Long Island Sound, New York, in October and moved south to Cape Lookout, North Carolina, before moving northeast a distance of 2360 km.

Furthermore, by combining aerial survey observations off the U.S. east coast (Shoop and Kenney 1992) and U.S. pelagic longline fleet captures (Witzell 1999), we know that large loggerhead turtles (mature and/or immature) routinely inhabit offshore habitats during non-winter months in the northwest North Atlantic Ocean. Some of these turtles might be associated with warm water fronts

FIG. 3. Carapace of large loggerhead sea turtle tied to the barrel of an 88 mm cannon aboard a German submarine in World War II. Photo from the U.S. National Archives and Records Administration, Washington, D.C.

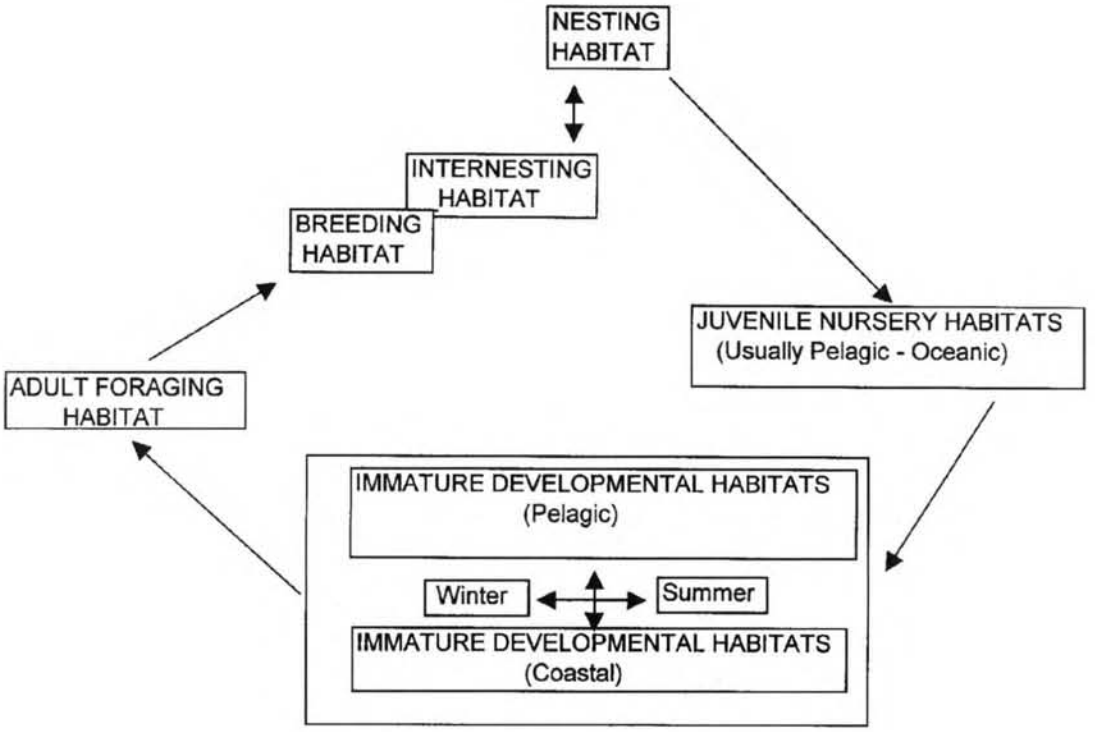

FIG. 4. Proposed conceptual model of loggerhead turtle development, showing seasonal movements between pelagic and coastal developmental habitats (modified after Musick and Limpus 1997).

and eddies associated with oceanic current systems such as the Gulf Stream and might form offshore feeding aggregations in areas of high productivity (Witzell 1999).

Historically, large immature pelagic loggerhead turtles were seemingly abundant between the Grand Banks and the Azores 50 years ago, before the declines in loggerhead turtle population of the 1970's (National Research Council 1990). German submarines reported seeing many large turtles swimming near their submarines during World War II near the Azores Islands (Wiggins 1999). While waiting for allied merchant shipping, crewmen would dive into the water after sundown, tie ropes to the turtles, and then pull them onto the U-boat deck. It is estimated from the photos that these turtles were approximately 65–75 cm (Figs. 2 and 3). The meat was used to make soups and the shells were kept as souvenirs.

Loggerhead turtles apparently have very complex life histories involving different developmental habitats. Australian loggerheads reportedly settle out of pelagic habitats at near mature sizes (79.8 cm SCL) and become residents of coastal feeding aggregations (Limpus et al. 1994). However, in the North Atlantic, the existence of later-stage immature pelagic loggerhead turtles either staying in or moving between coastal and pelagic habitats in the northwestern North Atlantic suggests the possible need for refinements to the current conceptual developmental models of Miller (1997) and Musick and Limpus (1997). The proposed new model is modified after Musick and Limpus (1997) and includes the addition of probable seasonal movements of immature turtles between pelagic and coastal developmental habitats (Fig. 4). Commonly used terms such as "coastal benthic" and "settlement lines" might be misleading and should be revised or used with caution.

Acknowledgments.—I thank Capt. Glenn Sytko for the photograph of the turtle on the U-boat deck. I also thank A. Bass, B. Bowen, M. Bresette, S. Epperly, C. Ruckdeschel, J. Schmid, J. Seminoff, R. Shoop, and an anonymous reviewer for reviewing early drafts of the manuscript.

Lizards of the New World genus *Anolis* have been extensively studied on Caribbean islands (e.g., Creer et al. 2001; Giannasi et al. 1997; Howard et al. 1999; Losos 1996) and the North American mainland (Guyer 1988a, 1988b; Guyer and Savage 1986, 1992; Vitt et al. 1995). Numerous ecological and life history studies of *Anolis* have focused on Caribbean taxa (Andrews 1976, 1979, 1991; Losos 1996; Ruibal et al. 1972; Schoener 1968; Schoener and Gorman 1968; Schoener and Schoener 1971a, 1971b). In contrast, few ecological studies of Mexican anoles have been carried out (e.g., Ramírez-Bautista 1995; Ramírez-Bautista and Vitt 1997), as most studies of Mexican anoles have been systematic (e.g., Campbell et al. 1989a; Fitch 1978; Fitch and Henderson 1973; Guyer and Savage 1986, 1992; Nieto-Montes de Oca 1994, 1996; Smith 1968a, 1968b, 1968c; Smith and Paulson 1968). Among Mexican anoles, significant life history data are available only for *A. nebulosus* populations from the Pacific coast (Jenssen 1970; Ramírez-Bautista 1995; Ramírez-Bautista and Vitt 1997), and only spotty ecological data exist for other species (e.g., *Norops uniformis*: Campbell et al. 1989b). As few data have become available since Fitch (1982) emphasized the paucity of reproductive information on Mexican anoles, we take this opportunity to report reproductive data on the rarely observed gray anole, *Anolis quercorum*, from Zapotitlán de las Salinas in the state of Puebla, México. As human activities have substantially altered the habitats from which this species is recorded, additional opportunities to obtain data on this species might be tenuous. In particular, we provide data on egg development, size, and volume; and relative clutch mass from a sample of four adult females, and reproductive condition for two males.

Zapotitlán de las Salinas is a small town in the southeastern portion of the state of Puebla at 1420 m elevation (18°07'18"N, 97°19'24"W; Villaseñor et al. 1990). The climate is dry and temperate (mean annual air temperature 21°C; range: 17–24°C) with most precipitation occurring during summer (mean annual precipitation = 450 mm; Secretaría de Gobernación 1988). A patchwork of thorn forest, xerophyllic brushland, and deciduous tropical dry forest remnants dominate local vegetation (Rzedowski 1981) within a matrix heavily influenced by human activities.

[a]Snout–vent length
[b]Non-vitellogenic follicles; number represents the sum from both ovaries

We collected six adult *A. quercorum* during the interval May–September 1998 (Table 1). Lizards were humanely killed, fixed in 10% formalin, and necropsied. We obtained linear measurements for snout–vent length (SVL) to the nearest 1.0 mm, length and width of the right testis in males, length and width of the left and right vitellogenic follicles (VF), and oviductal eggs (OE) in females, all to the nearest 0.1 mm. For females, we also recorded the number of nonvitellogenic follicles. We obtained the body weight of lizards with a 5-g Pesola™ scale to the nearest 0.05 g and the mass of each egg to nearest 0.01 g with an analytical balance. Length and width of the right testis were used to calculate its volume using the formula for an ellipsoid (Selby 1965); oviductal egg size was determined using the model of Maritz and Douglas (1994); and relative clutch mass (RCM) was determined using the method of Vitt and Price (1982). Volumetric data are reported to the nearest 0.1 mm^3. Unless otherwise noted, means are ± 1 SE. Specimens were deposited in the Laboratorio de Ecología de la Unidad de Biología, Tecnología, y Prototipos (UBIPRO), FES-I, Universidad Nacional Autónoma de México.

One male was captured on 14 May (JLE 2551) and 22 September (LOL 015). The male from 14 May had a smaller mass, but a considerably larger testicular volume, and had displayed greater reproductive activity than the male captured on 22 September (Table 1). These data suggest that reproductive activity might be greater in May.

Two adult females caught in July and September had body sizes and masses bracketing those of the two males (Table 1). The females obtained in September each carried an egg in each oviduct and one VF simultaneously (Table 1). In each case, the right OE was larger (JLE 3024: 11.6 x 6.3 mm; LOL 014: 11.0 x 6.5 mm) than the left (JLE 3024: 9.6 x 5.8 mm; LOL 014: 9.9 x 5.2 mm; see also Table 1), and a smaller VF was present (JLE 3024: 3.3 x 2.7 mm; LOL 014: 5.3 x 3.8 mm). In contrast, both females collected on 12 July carried only one OE (JLE 3004: 9.5 x 5.7 mm; JLE 3005: 10.5 x 5.8 mm), and only JLE 3005 had a smaller VF (5.9 x 4.7 mm) present. Moreover, the single OEs carried by July females were somewhat smaller in size and mass than the largest OEs of September females. This suggests that September females were pre-oviposition, whereas July females were post-oviposition. Mean OE volume was 199.5 ± 18.4 mm^3 (N = 6), mean VF volume was 40.2 ± 16.0 mm^3 (N = 3), and mean RCM was 0.122 ± 0.019 (N = 6).

Albeit limited, our data imply seasonal reproduction for *Anolis quercorum* similar to that reported for *A. nebulosus* (Jenssen 1970; Ramírez-Bautista 1995; Ramírez-Bautista and Vitt 1997). However, *A. quercorum* differs in seasonally simultaneously carrying two oviductal eggs and one vitellogenic follicle. This differs from the reproductive cycle in *A. nebulosus*, which lays an egg while an advanced vitellogenic follicle is ready to be ovulated (Ramírez-Bautista 1995). Data are too few to evaluate whether this difference reflects phylogeny or the altered habitat in which we found *A. quercorum*. Small differences in size between eggs in the right and left oviducts might indicate that the interval between ovipositions is shorter than in *A. nebulosus* (Ramírez-Bautista and Vitt 1997), but similar to that of *Norops uniformis* (Campbell et al. 1989b), *A. carolinensis* (Andrews 1985), and other island and mainland anoles (Andrews 1979). Relative clutch mass is low like other anoles (Vitt and Price 1982), but higher than in *A. nebulosus* (Ramírez-Bautista 1995). Additional data are needed to understand how this species' reproductive cycle might reflect its human-altered environment.

Acknowledgments.—We thank Hobart M. Smith for sending us literature on this species, Manuel Espino for his help in the field, Julio Lemos for allowing us to use specimens collected by V. Mata-Silva, Marc P. Hayes for editorial suggestions, and the Dirección General de Apoyo al Personal Académico (Proyecto # IN208398-DGAPA) for funding.

How does one test the validity of a population enumeration technique? Most validation studies perform "soft" validation; they attempt either to correlate the counts from two or more methods (Fitch 1992) or to compare the economic costs, difficulty, time requirements, or non-economic costs of carrying out selected methods (Strong et al. 1993). Soft validation does not establish the accuracy of a method. "Hard" validation, in which population estimates are checked against the true values, is obviously desirable, but it is always difficult to do and might be impossible for some systems. Hard validation studies involving reptiles or amphibians are rare and usually involve the artificial stocking of a bounded plot (Henke 1998; Rose and Armentrout 1974).

Distance sampling is a relatively new technique (Buckland et al. 1993) that has gained considerable favor for certain herpetological sampling problems (Akin 1998; Thompson et al. 1998), but has yet to be subjected to hard validation tests for reptiles or amphibians. As with strip transect searches (Duellman 1987), distance sampling involves searching for animals within a certain distance from a transect centerline, but it differs from strip transects in requiring the measurement (or estimation) of the perpendicular distance from the centerline to each detected animal. Whereas strip transect searches make the implicit assumption that detection is complete for animals within the strip, distance sampling requires only that all animals *near the centerline* be detected. The distribution of sighting distances to animals off the centerline is used to model detectability in the vicinity of the centerline, but it is only the centerline density estimate that is used and extrapolated to the habitat at large.

Because the centerline density is extrapolated to the overall habitat, it is essential that the centerline conditions be representative of the habitat. Strip transects make a similar assumption about the representativeness of the entire strip, but the corresponding distance sampling assumption is more problematic in that the centerline of many transects is a road or trail, hardly representative of adjacent habitat. In addition to having different ground cover

STORERIA DEKAYI DEKAYI (Northern Brownsnake) and ***S. OCCIPITOMACULATA OCCIPITOMACULATA*** (Northern Red-bellied Snake). **MORPHOLOGY**. Apical pits are reportedly absent in snakes of the genus *Storeria* (Boulenger 1893–1896. Catalogue of Snakes in the British Museum (Natural History). 2nd ed. 3 vols. Taylor and Francis, London. 727 pp.; Trapido 1944. Amer. Midl. Nat. 31:1–84.; Wright and Wright 1957. Handbook of Snakes of the United States and Canada. 2 vols. Comstock Publ. Co., Ithaca, New York. 640 pp.; Marx and Rabb 1972. Fieldiana Zool. 63:92–99). Herein, I report on the discovery of apical pits in two species of *Storeria*.

As part of an ongoing project dealing with the identification of shed skins, I examined 145 sheds of 21 species of North American snakes. Of the 145 sheds, six *S. d. dekayi* and eight *S. o. occipitomaculata* sheds were included for study. After being cut into sections and mounted, sheds were examined using a stereo microscope under 10x and 30x magnification. Data for various characters, including the presence or absence of apical pits were recorded. Two *S. d. dekayi* and four *S. o. occipitomaculata* sheds had apical pits on scales on the dorsal neck region (Fig.1), whereas scales beyond the nape had no observable pits.

Several factors may have been responsible for apical pits being overlooked in *Storeria* for so long. First, apical pits may be restricted and or more apparent on certain areas of the body (e.g., some specimens of *Lampropeltis triangulum*; Williams 1978. Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. Publ. Biol. Geol. Milw. Publ. Museum 2:1–258). Second, apical pits are best seen in shed skins (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. SSAR, Oxford, Ohio. 614 pp.). Also, it is evident that significant interspecific and intraspecific variation occurs in some groups (Ball 1996. Reptile & Amphibian Magazine. July/Aug 1996:112–116); less than half (43%) of the *Storeria* sheds in the present study had observable apical pits. The techniques used to prepare (e.g., mounting) and examine (e.g., intensity and angle of lighting) shed skins or actual specimens may affect how easily these structures are observed. If a structure is reported as absent, some may choose not to look for them. Intraspecific variation in the occurrence of apical pits warrants additional study.

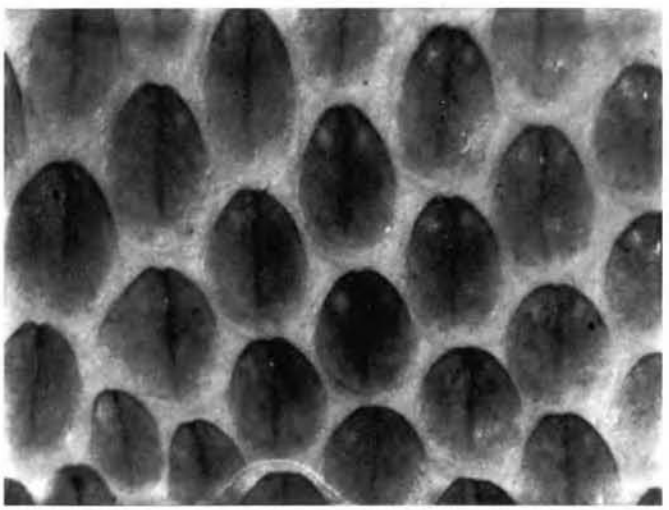

FIG. 1. Dorsal scales with apical pits on a shed skin of *Storeria dekayi dekayi* from Erie Co., Pennsylvania, USA.

I thank Brian Wettekin and Paul Curtis for providing field collected sheds, Hobart Smith for help with the literature and reviewing an earlier version of the manuscript, James Ball for confirming the presence of apical pits on the *Storeria* sheds, providing the microphotograph, and for reviewing a draft of the manuscript. I also thank James Harding whose suggestions were helpful in the final preparation of the manuscript.

Submitted by **BRIAN S. GRAY**, 1217 Clifton Drive, Erie, Pennsylvania 16505, USA.

XENOPELTIS UNICOLOR (Asian Sunbeam Snake). **DIET.** Tooth morphology of *Xenopeltis unicolor* is specialized for handling lizard prey (e.g., skinks; Greene 1997. Snakes: The Evolution of Mystery in Nature. Univ. California Press, Berkeley. 351 pp.). We report the first occurrence of oophagy by *X. unicolor*. An adult male *X. unicolor* (774 mm SVL) had two unidentified squamate eggs, measuring 23 and 29 mm in length, in its stomach. Each egg had been slit along the side one or more times and was empty. The snake was collected by Kamuran Tepedelen in central Java, Indonesia in June 1999. Both the *X. unicolor* and its stomach contents are part of the herpetological collections at the University of Michigan Museum of Zoology (UMMZ 227200 and UMMZ 227201, respectively).

Submitted by **KATHERINE A. DARIN** and **GLENN M. FOX**, Department of Ecology and Evolutionary Biology and Division of Reptiles and Amphibians, University of Michigan Museum of Zoology, Ann Arbor, Michigan 48109-1079 USA (e-mail: foxg@umich.edu).

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 33, Number 1 (March 2002). Additional note: The responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extensions unless a thorough literature review has been completed.

CAUDATA

AMBYSTOMA TIGRINUM (Tiger Salamander). USA: NORTH DAKOTA: DICKEY CO: State Hwy 11, 16.9 km E Ellendale (46°00'N, 98°19'W). 20 July 1999. Dean A. Croshaw. Sam Noble Oklahoma Museum of Natural History (OMNH 38270). Verified by Janalee P. Caldwell. Branchiate adult found on road. First county record (Hoberg and Gause 1992. North Dakota Outdoors 55:7–19).

Submitted by **DEAN A. CROSHAW**, Department of Zoology, University of Oklahoma, 730 Van Vleet Oval, Norman, Oklahoma 73019, USA; e-mail: croshaw@srel.edu.

AMBYSTOMA TIGRINUM MAVORTIUM (Barred Tiger Salamander). MÉXICO: CHIHUAHUA: Reservoir at La Bamba (30°5'47.4"N, 105°24'55.0"W), 1330 m elev. 8 June and 30 July 2001. Julio A. Lemos-Espinal. ANEIDES AENEUS (Green Salamander). USA: GEORGIA: Stephens Co: Panther Creek Cove, Chattahoochee National Forest, 8.8 km NNW of Toccoa. 27 November 2001. Matthew J. Elliott and Carlos D. Camp. Verified by M. E. McGhee. Photographic record placed in the Georgia Museum of Natural History (GMNH 46876). Rock outcrop in deciduous cove forest at 280 m elev. New county record and first record for Piedmont physiographic province in Georgia. At minimum reported elevation for eastern isolate (Corser 2001. Biol. Cons. 97:119–126). Site is unusual for Blue Ridge/Piedmont in having outcrops of limestone (Wharton 1978. The Natural Environments of Georgia, Georgia Department of Natural Resources).

Submitted by **MATTHEW J. ELLIOTT**, Georgia Gap Analysis Program, Institute of Ecology, University of Georgia, Athens, Georgia 30602, USA, and **CARLOS D. CAMP**, Department of Biology, Piedmont College, Demorest, Georgia 30535, USA.

DESMOGNATHUS AENEUS (Seepage Salamander). USA: GEORGIA: Pickens Co: Big Canoe Development, McDaniel Meadows, a conservation easement held by North American Land Trust (34.46241081N, 84.26860222W). 27 March 2002. Christopher R. Wilson. Georgia Museum of Natural History (GMNH 46878). Verified by Elizabeth McGhee. First county record (John Jensen, pers. comm.). Three individuals observed. Two were females found tending separate clutches of eggs under sphagnum moss at edge of small creek in wetland. Photographed and released. Funding for biological surveys provided by Big Canoe Company, LLC.

Submitted by **CHRISTOPHER R. WILSON**, 425 Roxanna Street, Boone, North Carolina 28607, USA; e-mail: critterfro@boone.net.

DICAMPTODON COPEI (Cope's Giant Salamander). USA: OREGON: Wasco Co: Boulder Creek, just above Forest Rd. 48. UTM's 5004876 m N, 616357 m E. 951 m elev., 9 September 2001. Charlotte Corkran. Verified by Keith B. Aubry. UWBM 2311. Specimen is a large, paedomorphic adult (96.5 SVL, 180 TL, 18.6 g). New county record and first record of this species east of the Cascade crest in Oregon. This is the southernmost and easternmost locality for this species, extending the range ca. 24 km SE of the Still Creek, Oregon, locality (Nussbaum 1976. Misc. Publ. Zool., Univ. Michigan 149:1–94). It is ca. 2 km further E than the only known eastside Washington locality, Spring Creek, Skamania Co. (Leonard et al. 1998. Herpetol. Rev. 29:244). Five other *D. copei* were captured, photographed, measured, and released during two earlier visits to Boulder Creek (unpubl. data), but no *D. tenebrosus* were observed.

We thank Robert Penson, Mt. Hood National Forest, for conducting stream surveys in the Oregon Cascades and first recognizing *D. copei* from Wasco County. We thank M. Hayes for reviewing this note.

Submitted by **LAWRENCE L. C. JONES**, USDA Forest Service, Pacific Northwest Research Station, Olympia, Washington 98512, USA (e–mail: ljones02@fs.fed.us), **CHARLOTTE CORKRAN**, Northwest Ecological Research Institute, Portland, Oregon 97229, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: ILLINOIS: Knox Co: Green Oaks, Knox College Biological Field Station: 6.5 km S of Victoria. 19 April 2001. Mathys J. Meyer and John A. Crawford. Verified by Christopher A. Phillips. Illinois Natural History Survey (INHS 17233). New county record for this state threatened species (Phillips et al. 1999. Field Guide to the Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.). Single specimen collected under a log, partially submerged in a seep originating from Lake Sharvy, in secondary oak-hickory forest. This represents the first voucher specimen for a population initially reported by Schramm and Nordgren (1978. Trans. Illinois Acad. Sci. 60:243) and discussed by Anton et al. (1998. *In* M. J. Lannoo [ed.], Status and Conservation of Midwestern Amphibians, pp. 45–48. Univ. of Iowa Press, Iowa City, Iowa). The population was believed extirpated following the drought of the late 1980s (Schramm, pers. comm). In October 1999 a specimen was discovered by Stuart Allison, however, it could not be collected due to the status of the species in Illinois. Additional specimens (N = 11) were found in various locations at Green Oaks in 2000 and 2001. This specimen was collected under a general endangered species permit (#00-20S) issued to Mathys J. Meyer and John A. Crawford by the Illinois Department of Natural Resources.

Submitted by **MATHYS J. MEYER** (e-mail: altboer@hotmail.com), Department of Biological Sciences, Illinois State University, Normal, Illinois 61790, USA; **JOHN A. CRAWFORD** (e–mail: jac7vc@mizzou.edu), Division of Biological Sciences, University of Missouri, Columbia, Missouri 65211, USA; and **STUART ALLISON** (e–mail: sallison@knox.edu), Biology Department, Knox College, Galesburg, Illinois 61401, USA.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). USA: ILLINOIS: Washington Co: in rotten log on bluff above Little Muddy River, 0.98 km E of the RR crossing in Dubois (38°13'56"N, 89°12'02", 490 m elev.). 15 May 2001. Raymond Thompson. Verified by Ralph Axtell. Southern Illinois University, Edwardsville Herpetology Collection (SIUE 2831). New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8, Champaign, Illinois. xii + 282 pp.).

Submitted by **AMY WISNESKI**, Department of Biological Sciences, Southern Illinois University Edwardsville, Illinois 62025, USA.

PLETHODON VENTRALIS (Southern Zigzag Salamander). USA: TENNESSEE: Fentress Co., Poplar Cove region, ca. 8 km W of Jamestown on the south side of State Hwy 52 on a private farm (36°26'30"N, 84°59'47"W). 22 March 2002. Vincent A. Cobb. Verified by A. Floyd Scott. Austin State University Museum of Zoology (APSU 3327). Two adults, one male and one female, were found under a 30–40 cm diameter limestone rock at the edge of a woodland. The male was captured and preserved as the voucher. Since approximately1986, I have observed this species several times under rocks in this woodland; always during winter or early spring when the soil is moist. New county record and extension of range into the Cumberland Mountains where status of this species is poorly known (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Austin Univ. Misc. Publ. 12:1–94).

Submitted by **VINCENT A. COBB**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

ANURA

ALSODES GARGOLA (NCN). ARGENTINA: CHUBUT: Departamento Futaleufú: Los Alerces National Park, 0.5 km N of Laguna Neira (42°39'34"S, 71°38'07"W), ca. 1120 m elev. 3 January 2002. C. Úbeda. Juvenile (SVL 26.5 mm). Museo de Ciencias Naturales de La Plata, La Plata, Argentina (MLP A 3312). Specimen was collected under a rock, at the edge of a shallow mountain stream, in a temperate deciduous forest of lenga (*Nothofagus pumilio*). Juveniles and tadpoles of the species were common. Población Neira, E shore of Rivadavia Lake (42°38'36"S, 71°40'18"W), ca. 550 m elev. 3 January 2002. C. Úbeda. Adult male (SVL 55 mm). Fundación Miguel Lillo, Tucumán, Argentina (FML 11272, color slide). Specimen was found under a log in a mountain stream in a temperate humid evergreen forest of coihue (*Nothofagus dombeyi*). Both specimens verified by N. Basso. Species is endemic to northwestern Argentinian Patagonia. It ranges from the volcanic tablelands of Lonco Luan, province of Neuquén (38°52'S, 70°34'W) (Cei 1980. Amphibians of Argentina. Monit. zool. ital. [N.S.], Monogr. 2:[I–xii] + 1–609) to La Hoya, Cordón de Esquel, province of Chubut (Úbeda 2000. Herpetol. Rev. 31:181) but its distribution is scattered. These are the first records for Los Alerces National Park and the second provincial records, and constitute a range extendion of 39–42 km NW from the first record at La Hoya (Úbeda, *op.cit.*).

Submitted by **CARMEN A. ÚBEDA**, Centro Regional Bariloche, Universidad Nacional del Comahue, Unidad Postal Universidad, R 8400 FRF Bariloche, Prov. de Río Negro, Argentina.

BATRACHYLA ANTARTANDICA (NCN). ARGENTINA: CHUBUT: Departamento Cushamen: Lago Puelo National Park, 1 km N of Lake Puelo shore, near trail to Los Hitos (42°06'S, 71°42'37"W), ca. 350 m elev. 26 January 2002. Félix Vidoz. Museo de La Plata, La Plata, Argentina (MLP A 3313). Adult male (SVL 35.6 mm). Verified by Néstor G. Basso. Specimen was calling at time of capture. Specimen was collected in a small bog with abundant ferns (*Blechnum chilense*) and some elements of Valdivian flora (*Lomatia ferruginea*, *Caldcluvia paniculata*, and *Weinmania trichosperma*) near Fuinque stream. This area was surrounded by a mixed temperate forest dominated by coihue (*Nothofagus dombeyi*), ciprés de la cordillera (*Austrocedrus chilensis*), and radal (*Lomatia hirsuta*). This site also supports populations of *Eupsophus calcaratus*, *E. emiliopugini*, *Pleurodema thaul*, *Batrachyla leptopus*, *Alsodes gargola*, and *A. monticola*. Another male specimen was found 6 km SW (42°8'48"S; 71°45'3"W), ca. 820 m, in a small *Sphagnum* bog, near Melo stream, in a humid forest with *N. dombeyi* and alerce (*Fitzroya cupressoides*).

This species is known from austral forests of Chile and Argentina, with a narrow distribution along the eastern slopes of the Andes. Few records for this species exist from Argentina: at Nahuel Huapi National Park (S of Neuquén Province and N of Río Negro Province) (Barrio 1967. Physis [Buenos Aires] 27[74]:101–109) and one record for Chubut Province at La Plata Chico Lake (Úbeda 2000. Herpetol. Rev. 31:109). This is the first record for Lago Puelo National Park and the second one for Chubut Province, and decreases the distributional gap between northern and southern localities in Argentina.

Submitted by **FÉLIX VIDOZ**, Administración de Parques Nacionales, Intendencia Parque Nacional Lago Puelo, (U9211ADA) Lago Puelo, Chubut, Argentina, **CARMEN A. ÚBEDA**, Centro Regional Bariloche, Universidad Nacional del Comahue, Unidad Postal Universidad, R 8400 FRF Bariloche, Prov. de Río Negro, Argentina, and **JULIÁN Q. VIDOZ**, Villa del Lago, (U9211ADA) Lago Puelo, Chubut, Argentina.

BATRACHYLA NIBALDOI (Nibaldo's Wood Frog). CHILE: XI REGION DE AYSEN: Aysén Province, Las Guaitecas National Reserve: Kent Island: Beach toward the Channel Ninualac, 45°04'15"S, 74°22'21"W. 21 March 2002. Juvenile specimen collected on mosses near a beach. Museo de Zoología de la Universidad de Concepción (MZUC 26753). 45°04'13"S, 74°17'7"W. 24 March 2002. Mature female (SVL 48.6 mm) collected on mosses in a Chilean valdivian rain forest dominated by tepuales (*Tepualia stipularis*) and canelos (*Drimys winteri*) (MZUC 26754). Both verified by J. C. Ortiz. Species known in Chile from Puente Traihuanca (46°25'S, 72°04'W) (Formas 1997. Herpetologica 53:6–13) and from Laguna San Rafael National Park (Díaz-Páez and Williams 2001. Herpetol. Rev. 32:189. Extends the range of this species ca. 190 km N and W of the Puente Traihuanca record. In this area *B. nibaldoi* coexists with *Batrachyla antartandica, Eupsophus emiliopugini*, and *E. calcaratus*.

Submitted by **HELEN DÍAZ PÁEZ,** Departamento de Zoología, Facultad de Ciencias Naturales y Oceanográficas, Universidad de Concepción, Casilla 160-C, Concepción, Chile, and **ESTEBAN CARREÑO,** Museo Nacional de Historia Natural, Casilla 787, Interior Quinta Normal, Santiago, Chile.

BUFO ATACAMENSIS (Atacama Toad; Sapo de Rulo). CHILE: II Region (Antofagasta): Quebrada de los Sapos also known as Los Perales (25°02'S; 70°27'W), 6 km E of the little fishing town of Paposo. 2 August 1996 (DBGUCH: 2200–2208); Las Bandurrias gorge (25°12'64"S; 70°26'25"W). 2 August 1996 (DBGUCH: 2101, 2092). III Region (Atacama): Las Chilcas in the Pan de Azúcar National Park. (26°03'S; 70°33'W). 1 April 1997 (DBGUCH: 2246–2247); La Finca of Chañaral (26°38'01"S; 69°51'38"W), 30 km NE of the mining town of Finca de Oro, 1 April 1997 (DBGUCH: 2303, 2308). IV Region (Coquimbo): Socos (30°45'S; 71°30'W), 37 km SW of Ovalle, next to Limarí River. 30 August

1996 (DBGUCH: 2079). Pajonales (29°38'S; 71°30'W), 80 km N of the city of La Serena. 19 August 1996 (DBGUCH: 2071, 2078, 2140, 2160, 2165, 2168). All specimens collected by M. Sallaberry and M. Méndez, and verified by A. Veloso, and were deposited in the herpetological collection of Departamento de Biología Celular y Genética de la Universidad de Chile (DBGUCH). This new information includes precise localities in northern part of the range and extends the southern limit of the distribution previously described by Cei (1962. Batracios de Chile, Ediciones Universidad de Chile) more than 100 km. These new localities have been recorded with the support of Grants Fondecyt 5960021–96 and 2960012–96.

Submitted by **MICHEL SALLABERRY** (e–mail: msallabe@uchile.cl) and **MARCO A. MENDEZ** (e-mail: mmendez@icaro.dic.uchile.cl) Departamento de Ciencias Ecológicas, Facultad de Ciencias, Universidad de Chile, PO Box 653, Santiago, Chile.

BUFO VALLICEPS (Gulf Coast Toad). USA: TEXAS: DENTON Co: Cicada Trail, Lewisville Lake Environmental Learning Area (33°03'56.1"N, 96°58'30.6"W; datum WGS 84). 23 November 2001. Joel A. Johnson. Verified by Janalee P. Caldwell. OMNH 39074–81. New county record; connects northernmost record (Grayson Co., Texas) with contiguous southern distribution (Dixon 2000. Amphibians and Reptiles of Texas. Second Edition. Texas A&M Univ. Press, College Station. 421 pp.). Specimens found along maintained trail under wooden ties in bottomland habitat adjacent to Elm Fork of the Trinity River below Lake Lewisville Dam.

Submitted by **JOEL A. JOHNSON**, Department of Zoology, University of Oklahoma, 730 Van Vleet Oval, Norman, Oklahoma 73019, USA e–mail: pliscan@ou.edu.

CHIASMOCLEIS CARVALHOI (Central Humming Frog). BRAZIL: BAHIA: Una Municipality (15°18'S, 39°04'W). 28 m elev. 06 October 1999–25 February 2000. M. Dixo. Museu Nacional, Rio de Janeiro (MNRJ 28605–24). Porto Seguro Municipality: Reserva Particular do Patrimônio Natural (RPPN) Estação Veracruz (16°23'S, 39°10'W). 82 m elev. 20–22 June 2001. B. V. S. Pimenta. MNRJ 28957–59. 12 July 2001. B. V. S. Pimenta. MNRJ 28960–61. 13 September 2001. B. V. S. Pimenta. MNRJ 28962. Verified by José Perez Pombal, Jr. and Ulisses Caramaschi. All specimens were captured with pitfall traps. According to Cruz et al. (1997. Alytes 15[2]:49–71), *Chiasmocleis carvalhoi* is found in lowland forests in the states of Rio de Janeiro and São Paulo, in the southeast region of Brazil. This new record for the state of Bahia extends the range ca. 960 km and suggests a possible disjunct distribution for this species.

Submitted by **BRUNO V. S. PIMENTA** (e-mail: brunopimenta@softhome.net), **CARLOS ALBERTO GONÇALVES DA CRUZ** (e-mail: cagruz@uol.com.br), Departamento de Vertebrados, Museu Nacional do Rio de Janeiro, Quinta da Boa Vista, 20940-040, Rio de Janeiro, RJ, Brazil; and **MARIANNA DIXO,** Universidade de São Paulo, Instituto de Biociências, Departamento de Ecologia, C.P. 11461, CEP 05422-970, São Paulo, SP, Brazil (e-mail: maridixo@ib.usp.br.).

CHIASMOCLEIS SCHUBARTI (Schubart's Humming Frog). BRAZIL: BAHIA: Guaratinga Municipality: Fazenda Vista Bela (16°36'S, 39°55'W, 320 m elev.). 14 September 2000. B. V. S. Pimenta, R. T. Moura, A. Paglia, and R. V. Lopes. Museu Nacional, Rio de Janeiro (MNRJ 29773). Porto Seguro Municipality: Reserva Particular do Patrimônio Natural (RPPN) Estação Veracruz (16°23'S, 39°10'W, 82 m elev.). 20 June 2001. B. V. S. Pimenta. MNRJ 27256. 10–11 July 2001. B. V. S. Pimenta. MNRJ 28894–97. 23 August 2001. B. V. S. Pimenta. MNRJ 28875. 27 October 2001. B. V. S. Pimenta. Museu de Ciências Naturais at Pontifícia Universidade Católica de Minas Gerais, Belo Horizonte (MCN 2912–13). Porto Seguro Municipality: Parque Nacional Pau Brasil (16°31'S, 39°18'W, 80 m elev.). 16 September 2001. D. L. Silvano and B. V. S. Pimenta. MNRJ 28907–08. Verified by Ulisses Caramaschi and Carlos Alberto Gonçalves da Cruz. Published distribution, according to Cruz et al. (1997. Alytes 15[2]:49–71), is Atlantic Rainforest fragments in the states of Minas Gerais and Espírito Santo, in the southeast region of Brazil. This new record for the state of Bahia establishes a new northern limit of distribution for this species and extends range ca. 302 km.

Submitted by **BRUNO V. S. PIMENTA** (e–mail: brunopimenta@softhome.net) and **DÉBORA L. SILVANO** (e-mail: dsilvano@softhome.net), Instituto de Estudos Sócio-Ambientais do Sul da Bahia/Universidade Federal de Minas Gerais, Laboratório de Manejo de Fauna, Depto. Zoologia/ICB, 31270-901, Belo Horizonte, MG, Brazil.

COLOSTETHUS TEPUYENSIS (NCN). VENEZUELA: ESTADO BOLÍVAR: MUNICIPIO GRAN SABANA: Forest at right margin of Cucurital River, between Wareipita River and Wareipa rapids (6°00'36"N, 62°47'27"W). 390 m elev. 14 April 1999. C. Molina. Museum of Natural History La Salle (MHNLS 14405). Purumay-vená, waterfall at Purumay River, tributary of Cucurital River (5°52'48"N, 62°45'22"W). 445 m elev. 5–9 April 2000. C. Molina, E. La Marca, and J. C. Señaris. MHNLS 14914, 14924–14926, 14940–14941. Verified by J. Ayarzagüena. First report of the species outside the type locality (La Marca 1996. Publ. Asoc. Amigos Doñana 9:1–64), extends known distribution ca. 40 km NE from the type locality near Kamarata, on the southeastern slopes of the Auyán-tepui. Specimens were collected during daytime in a small rocky stream in the forest, among the leaf litter and along the spray zone of this waterfall. With the exception of *Colostethus brunneus*, a frog apparently having a wide distribution in the Amazonian lowlands, all Venezuelan-Guayanan *Colostethus* appear to have very restricted distributions. The new localities lie within the Auyán-tepui area, one of the most biologically diverse centers in the Pantepui region (Huber 1986. Interciencia 11:301–310).

ELEUTHERODACTYLUS DIASTEMA (NCN) HONDURAS: GRACIAS A DIOS: Bodega de Río Tapalwás (14°56'N, 84°32'W), 190 m elev. 11 and 13 October 2001. James R. McCranie and Kirsten E. Nicholson. USNM 549350–51. Crique Yulpruan (14°54'N, 84°3''W), 140 m elev. 14 October 2001. James R. McCranie and Kirsten E. Nicholson. USNM 549352. All verified by Larry D. Wilson. First record for Honduras, extending the range ca. 90 km N of Bonanza, Atlántico Norte, Nicaragua (Köhler 2001. Anfibios y Reptiles de Nicaragua. Herpeton, Offenback, Germany, 208 pp.). McCranie and Wilson (2002. The Amphibians of Honduras. SSAR Contrib. Herpetol. 19, 625 pp.) predicted that this species likely occurred in eastern Honduras. All specimens are males and were found while they called from the tops of palm leaves 1–3 m above the ground.

EUPSOPHUS EMILIOPUGINI (NCN). CHILE: XI REGION DE AYSEN: Aysén Province, Las Guaitecas National Reserve: Kent Island, (45°04'S, 74°22'W). 23 March 2002. Female (SVL 47.5 mm) collected in cavities in the soil in the Chilean temperate rain forest. Helen Díaz Páez. Museo de Zoología de la Universidad de Concepción (MZUC 26845). Melchor Island (45°10'S, 74°09'W). 26 March–3 April 2002. Three mature females (SVL [in mm] 51.2, 46.9, and 55.0). Adult specimens collected under logs in Chilean temperate rain forest dominated by tepual (*Tepualia stipularis*) and canelo (*Drimys winteri*). Helen Díaz Páez. (MZUC 26843–44, 26846). Four specimens verified by Juan Carlos Ortiz. Puerto Yates, Rivero Island (45°37'S, 74°22'W). 10 March 2001. Male (SVL 40.0 mm). José Nuñez. Instituto de Zoología, Universidad Austral de Chile (IZUA 3374). Verified by J. Ramón Formas. The historical distribution of this species in Chile extended from Puyehue (40°42'S, 72°18'W) to Caleta Vidal (45°16'S, 73°27'W) (Formas 1989. Proc. Biol. Soc. Washington 102[3]:568–576). The first four records reported herein extend the known range to the Chilean coast. The Rivero Island record extends the species range ca. 84 km S and W from the Caleta Vidal record.

Submitted by **HELEN DÍAZ PÁEZ,** Departamento de Zoología, Facultad de Ciencias Naturales y Oceanográficas, Universidad de Concepción, Casilla 160-C, Concepción, Chile, and **JOSE NUÑEZ** Instituto de Zoología, Universidad Austral de Chile, Casilla 567, Valdivia, Chile.

HYALINOBATRACHIUM NOURAGUENSIS (Glassfrog). BRAZIL: AMAZONAS: Presidente Figueiredo Municipality (02°09'3"S, 60°02'06.2"W), Private Reserve of Natural Patrimony (RPPN) Cachoeira da Onça. 1 September 2000. O. Pereira and A. C. Cordeiro-Duarte. Amphibian and Reptile Collection of National Institute for Amazonian Research (INPA 10.156). Verified by Ulisses Gallati. The adult male (21 mm SVL) was calling from a perch 3 m above ground in streamside vegetation 30 m downstream from a waterfall, in primary forest. This is the first record of this species from the Brazilian Amazon and extends distribution 1040 km SW of populations in French Guyana (Lescure and Marty 2000. Atlas des Amphibians de Guyane, M.N.H.N. Paris).

Submitted by **ANA C. CORDEIRO-DUARTE** and **TÃNIA M. SANAIOTTI**, Instituto Nacional de Pesquisas da Amazônia - INPA, Av. André Araújo, 2936, C.P. 478, Manaus, AM, 69.083-000, Brazil; **EMERSON L. HYLA ALBOPUNCTATA (NCN). BRAZIL: RIO GRANDE DO SUL: Municipality of Santa Maria: Campus da Universidade Federal de Santa Maria (29°43'S, 53°43'W) and vicinities (29°44'S, 53°44'W). 26 February and 14 March 2002. K. A. Kopp and T. G. dos Santos. Herpetology Collection, Departamento de Biologia, Universidade Federal de Santa Maria, Santa Maria (ZUFSM 2813, 2822–23). Verified by Paulo Christiano de Anchietta Garcia. First record from the Depressão Central in the state of Rio Grande do Sul. This extends the range 300 km from a previous record in the northwest state of Santo Antônio das Missões Municipality (28°30'S, 55°13'W) (Garcia and Vinciprova 1998. Herpetol. Rev. 29:117–118).

Submitted by **KATIA A. KOPP, TIAGO G. DOS SANTOS, RAFAEL TREVISAN, MARCIA R. SPIES,** and **SONIA T. Z. CECHIN,** Departamento de Biologia, Universidade Federal de Santa Maria, Faixa de Camobi, Km 9, Campus, Camobi, cep: 97105-900, Santa Maria, Rio Grande do Sul, Brazil (e–mail [STZC]: cechinsz@ccne.ufsm.br).

HYLA AVIVOCA (Bird–Voiced Treefrog). USA: ARKANSAS: Clark Co: 11.3 km SW Gurdon off Hwy 67, Sec. 13 T10S R22W. 21 April 2002. Tobin Fulmer. Henderson State University collection 1056–1057. Verified by Stan Trauth. Two specimens collected from a chorus of about a dozen, which were calling from a swampy area located northeast of the Little Missouri River. First record for Clark Co., extends range northwestward in the Ouachita River Valley and into the Little Missouri River drainage (Trauth1992. Proc. Arkansas Acad. Sci. 46:80–82).

Submitted by **TOBIN FULMER** and **RENN TUMLISON**, Department of Biology, Henderson State University, Arkadelphia, Arkansas 71999, USA.

HYLA CARVALHOI (Carvalho's Treefrog). BRAZIL: RIO DE JANEIRO: Santa Maria Madalena, Parque Estadual do Desengano (21°53'S, 41°55'W). 1750 m elev. 30 June 1989. R. B. Pineschi. Museu Nacional, Rio de Janeiro (MNRJ 16983). Verified by Ulisses Caramaschi. This is the first record outside the type-locality, Parque Nacional da Serra dos Órgãos, Teresópolis, Rio de Janeiro, Brazil (22°24'S, 42°57'W), and the northernmost for the species (aerial distance between the two localities ca. 110 km), both in Serra dos Órgãos, a regional designation for the Serra do Mar range.

Submitted by **MARCELO F. NAPOLI**, Departamento de Vertebrados, Museu Nacional, Quinta da Boa Vista, Rio de Janeiro, Rio de Janeiro 20940-040, Brazil; e–mail: napoli@acd.ufrj.br.

HYLA GIESLERI (Giesler's Treefrog). BRAZIL. SÃO PAULO: Municipality of Ubatuba, Núcleo Picinguaba (23°23'S, 44°50'W). 20 February 2002. M. T. Hartmann and P. A. Hartmann. Collection

Célio Fernando Baptista Haddad, Departamento de Zoologia, Universidade Estadual Paulista, Rio Claro, São Paulo State; Brazil. (CFBH 3969, adult male). Verified by C. F. B. Haddad. Species known from the lowlands of Espírito Santo and Rio de Janeiro State (Frost 2000. Amphibian Species of the World: An Online Reference [http://research.amnh.org/herpetology/amphibia]). First state record; extends known distribution up to 180 km S from Magé Municipality (22°39'S, 43°02'W), Rio de Janeiro State (Santos et al. 1998. J. Herpetol. 32:61–66).

Submited by **MARÍLIA T. HARTMANN** (e–mail: matal@rc.unesp.br) and **PAULO A. HARTMANN** (e–mail: pahart@rc.unesp.br), Pós Graduacao em Zoologia, Instituto de Biociências, Caixa Postal 199, UNESP, 13506-900 Rio Claro, São Paulo, Brazil.

HYLA VERSICOLOR (Gray Treefrog). CANADA: ONTARIO: KENORA DISTRICT. Hwy 804, 0.3 km NE of Ontario Power Generation's Manitou Falls Generating Station (UTM Zone 15: N5603600 m, E467800 m). 8 May 1993. Wayne F. Weller and Ron Sheehan. Royal Ontario Museum (ROM 32576 [segment 3], audio cassette tape). Verified by Ross D. MacCulloch. Three or four individuals calling at 2200 h from cattail pond (fog and drizzle, air temperature 17°C). An observation of a live adult male on Hwy 804 was made 1 km E at 2355 h, but specimen was not retained. The documented northern range limit in Kenora District of northwestern Ontario is represented by specimens from (west to east) Malachi (UTM Zone 15: N5535000 m, E355000 m, ROM 9686 – August 1947), Kenora Airport (UTM Zone 15: N5515900 m, E401600 m, JPB 24697 (J. P. Bogart, University of Guelph)– July 1995), Contact Bay in Wabigoon Lake (UTM Zone 15: N5505000 m, E515000 m, ROM 10049 – June 1963), and Butler (UTM Zone 15: N5479000 m, E581500 m, NMC 24517 – June 1983). Extends range 130 km NE of Malachi, and 110 km NW of Kenora airport. This is the northernmost record in Ontario.

Submitted by **WAYNE F. WELLER**, 250 Chercover Drive, Thunder Bay, Ontario P7G 1A2, Canada.

HYLODES SAZIMAI (NCN). BRAZIL: RIO DE JANEIRO: Itatiaia: Parque Nacional do Itatiaia (22°19'S 44°45'W). 6 February 2000. Paulo A. S. Nuin, Paulo C. A. Garcia. Coleção Herpetológica do Museu de Zoologia da Universidade de São Paulo - 96264-65. Verified by Célio C. F. Haddad. First record of the species for the state of Rio de Janeiro, extending 300 km NW from the type locality (Haddad and Pombal 1995. Herpetologica 51:280) in the state of São Paulo, Brazil.

Submitted by **PAULO A. S. NUIN,** Museu de Zoologia, USP, São Paulo, Brazil, 04263-000 (e-mail: nuin@ib.usp.br), and **PAULO C. A. GARCIA**, IB, UNESP, Rio Claro, Brazil, 13506-900.

LEPTODACTYLUS PETERSII (NCN). ECUADOR: PROVINCIA DE SUCUMBIOS: Sacha Lodge (0°26'33"S, 76°27'57"W). 280 m elev. 31 January–4 February 2001. W. Chris Funk. Museo de Zoologia de la Pontificia Universidad Católica del Ecuador (QCAZ 20242–7). Verified by W. R. Heyer. First record in Ecuador. Its presence was expected because the species is widely distributed throughout the Amazon Basin (Heyer 1994. Smithson. Contr. Zool. 546).

Submitted by **SANTIAGO R. RON**, Departamento de Biología y Centro de Biodiversidad y Ambiente, Pontificia Universidad Católica del Ecuador, Apartado Postal 17-01-2184, Quito, Ecuador; e-mail: sron@puceuio.puce.edu.ec.

LEPTODACTYLUS VIRIDIS (Jim's White-lipped Frog). BRAZIL: BAHIA: Guaratinga Municipality: Fazenda Vista Bela (16°36'S, 39°55'W). 320 m elev. 17 September 2000. B. V. S. Pimenta, R. T. Moura, A. Paglia, and R. V. Lopes. Museu Nacional, Rio de Janeiro (MNRJ 29605). Verified by Ulisses Caramaschi. Previously known only from the type locality, in the Municipality of Itagibá, Bahia state (Frost 2000. Amphibian Species of the World: An Online Reference. V2.20. American Museum of Natural History). A female specimen was found in the water, in wet cow pasture, on the borders of an Atlantic Forest fragment. This habitat was very similar to that described for the type series (Jim and Cruz 1979. Rev. Bras. Biol. 39[3]:707–710). Extends the range 244 km S of type locality.

Submitted by **DÉBORA L. SILVANO** (e–mail: dsilvano@softhome.net) and **BRUNO V. S. PIMENTA** (e–mail: brunopimenta@softhome.net), Instituto de Estudos Sócio-Ambientais do Sul da Bahia/Universidade Federal de Minas Gerais, Laboratório de Manejo de Fauna, D. Zool./ICB, 31270-901, Belo Horizonte, MG, Brazil.

ODONTOPHRYNUS OCCIDENTALIS (Cururu Lesser Escuerzo). ARGENTINA: CHUBUT: Departamento Telsen: 9.5 km E of Telsen (42°25'30"S, 66°49'25"W). Ca. 430 m elev. 21 February 2002. Silvana G. Peiretti and Néstor G. Basso. Five tadpoles and three juveniles. Herpetological collection, Museo de La Plata (MLP A 3315). Verified by Jorge D. Williams; Arroyo Verde, Departamento Biedma (42°S, 65°17'W). 200 m elev. 27 February 1973. Daniel Stiebel and Claudio Stiebel. Five juveniles. Department of Herpetology, Museo Argentino de Ciencias Naturales "Bernardino Rivadavia" (MACN 30346–50). Verified by Gustavo Carrizo. The southernmost population of *O. occidentalis* was known from the Somuncurá Plateau, at about 41°S in Río Negro Province (Ruiz et al. 1982. Cytogenet. Cell Genetics 33:303–311). Specimens collected at Telsen were found at a small stream in the arid Patagonian steppe, in sympatry and syntopy with the frog *Pleurodema bufoninum*. These vouchers represent the first records for the Province of Chubut, extending the known range of the species 150 km S from previously reported localities.

Submitted by **SILVANA G. PEIRETTI, NESTOR G. BASSO**, Centro Nacional Patagónico, Blvd. Brown s/n. 9120 Puerto Madryn, Chubut, Argentina, and **SERGIO D. ROSSET**, Instituto de Limnología "Dr. Raúl A. Ringuelet," cc 712, 1900 La Plata, Buenos Aires, Argentina.

PHASMAHYLA EXILIS (Mottled Leaf Frog). BRAZIL: BAHIA: Jussari Municipality: Reserva Particular do Patrimônio Natural (RPPN) Serra do Teimoso (15°08'S, 39°31'W). 17 July 2000. B. V. S. Pimenta and R. V. Lopes. Museu Nacional, Rio de Janeiro (MNRJ 28425). Verified by Carlos Alberto Gonçalves da Cruz. Known distribution was Atlantic Rainforest fragments in the state of Espírito Santo, in southeastern Brazil (Frost 2000. Amphibian Species of the World: An Online Reference. V2.20. American

Museum of Natural History). This specimen, an adult female, was collected in a forested area from a perch near a small dam. This is the first record of the genus for the northeast region of Brazil. It extends range ca. 555 km northward and establishes a new northern range limit (see Feio et al. 2000. Herpetol. Rev. 31:251).

Submitted by **BRUNO V. S. PIMENTA** (e-mail: brunopimenta@softhome.net) and **DÉBORA L. SILVANO** (e-mail: dsilvno@softhome.net), Instituto de Estudos Sócio-Ambientais do Sul da Bahia/Universidade Federal de Minas Gerais, Laboratório de Manejo de Fauna, Depto. Zoologia/ICB, 31270-901, Belo Horizonte, MG, Brazil.

PROCERATOPHRYS PHYLLOSTOMUS (Leaf-nosed Horned-frog). BRAZIL: ESPÍRITO SANTO: Santa Teresa: Valssugana Velha (ca. 19°57'22"S; 40°35'03"W). 680–800 m elev. 23 May 2000. Marcelo Passamani. Verified by C. A. Gonçalves da Cruz and E. Izecksohn. Museu de Biologia Professor Mello Leitão, Santa Teresa, Espírito Santo (MBML 1326). The species was known only from the type locality: Castelinho (ca. 20°30'40"S, 40°59'10"W), Cachoeiro do Itapemirim (now Vargem Alta), Espírito Santo, Brazil (Izecksohn et al. 1998. Revista Univ. Rural, sér. ciênc. vida. 20[1–2]:37–54). Specimen collected in a fragmented stretch of the Atlantic forest and is the third known specimen of *P. phyllostomus*. This record extends the species distribution ca. 65 km northward.

Submitted by **JOÃO LUIZ GASPARINI**, Departamento de Ecologia, Universidade Federal do Espírito Santo, Caixa Postal 5130, 29041-970 Vitória, Espírito Santo, Brazil; e-mail: gaspa.vix@terra.com.br.

PSEUDOPALUDICOLA LLANERA (Ranita Enana Llanera). VENEZUELA: ESTADO MÉRIDA: La Pedrera, Sector La Vueltosa, 5 km NW of Santa María de Caparo (07°44'N, 71°32'W). 16 August 2000. A. Chacón-Ortiz. Colección de Vertebrados, Facultad de Ciencias, Universidad de Los Andes, Mérida (CVULA 6490–91). Verified by Amelia Diaz de Pascual. With the exception of the original description (Lynch 1989. Copeia 1989:577–588), and a more recent account by Myers and Donnelly (2001. Bull. Am. Mus. Nat. Hist. 261:1–85) little is known of the distribution of this species in Venezuela. First state record and first locality north of the Orinoco River in Venezuela, ca. 400 km to the NW of nearest locality in Río Meta (Lynch, *op. cit.*).

Submitted by **CÉSAR LUIS BARRIO-AMORÓS**, Fundación AndígenA, Apartado Postal 210, 5101-A, Mérida, Venezuela (e-mail: cesarlba@yahoo.com) and **ANDRÉS CHACÓN-ORTIZ,** Fundación Bullfrog. 5101-A. Mérida, Venezuela (e-mail: aecortiz@yahoo.com).

SCINAX EURYDICE (Maracas Snouted Treefrog). BRAZIL: SÃO PAULO: Municipality of Ubatuba, Núcleo Picinguaba (23°23'S, 44°50'W). 27 July 2001. M. T. Hartmann. Collection Célio Fernando Baptista Haddad, deposited in Departamento de Zoologia, Universidade Estadual Paulista, Municipality of Rio Claro, São Paulo State; Brazil (CFBH 3936, adult male). Verified by I. Sazima and C. F. B. Haddad. Specimens were collected from perches at the margins of temporary ponds on the borders of a forest after rain. Published distribution for the species is southern Bahia to Rio de Janeiro State (Frost 2000. Amphibian Species of the World: An Online Reference [http://research.amnh.org/ herpetology/amphibia]). First state record, extends range ca. 250 km S from known distribution in Palmital, Municipality of Saquarema (22°50'S, 42°27'W), Rio de Janeiro State (Wogel et al. 2000. Bol. Mus. Nac., N.S., Zool., Rio de Janeiro 427:1–16).

Submited by **MARÍLIA T. HARTMANN** (e-mail: matal@rc.unesp.br), Pós Graduacao em Zoologia, Instituto de Biociências, Caixa Postal 199, UNESP, 13506-900 Rio Claro, São Paulo, Brazil.

SCINAX NASICA (NCN). BRAZIL: RIO GRANDE DO SUL: Municipality of Santa Maria: Camobi district: Campus da Universidade Federal de Santa Maria (29°42'S, 53°42'W) and vicinity. 23 September 2000, 2 March 2002, and 17 May 2002. S. T. Z. Cechin, T. G. dos Santos, and K. A. Kopp. Herpetology Collection, Departamento de Biologia, Universidade Federal de Santa Maria, Santa Maria (ZUFSM 2435–37, 2818, 3034). Verified by Paulo C. de Anchietta Garcia. These specimens represent the first vouchers from the Depressão Central in the state of Rio Grande do Sul and extend the range of the species ca. 500 km from the single specimen collected in Itaqui Municipality (29°20'S, 56°38'W) (Giasson 2001. Herpetol. Rev. 32:273).

Submitted by **SONIA T. Z. CECHIN, TIAGO G. DOS SANTOS, KATIA A. KOPP, MARCIA R. SPIES,** and **RAFAEL TREVISAN**, Departamento de Biologia, Universidade Federal de Santa Maria, Faixa de Camobi, Km 9, Campus, Camobi, cep: 97105-900, Santa Maria, Rio Grande do Sul, Brazil (e–mail [STZC]: cechinsz@ccne.ufsm.br).

THELODERMA HORRIDUM (NCN). WEST MALAYSIA: PAHANG: Pulau Tioman. Zoological Research Collection at The University of Singapore (ZRC) 01.9661. 19 March 2002. Jesse L. Grismer, Ricardo Escobar III, and Tim M. Youmans. Verified by L. Lee Grismer. Previously known from southern Thailand south to Singapore, Sumatra, and Borneo (Manthey and Grossmann 1997. Amphibien und Reptilien Südostasiens. Natur und Tier-Verlag, Münster. p. 139). This specimen constitutes a new island record (Grismer et al. 2002. Herpetol. Rev. 33:26–29). It was collected during the evening, from a 0.75 m diameter dipterocarp tree, ca. 3.5 m from the forest floor, in primary forest along a walking trail Kampung Tekek to Kampung Juara. When sighted, the specimen was leaning off the tree at a 45-degree angle; it then flattened against the tree in an attempt to hide.

Submitted by **JESSE L. GRISMER** (e-mail: jessgris@lasierra.edu), **RICARDO A. ESCOBAR III**, and **TIM M. YOUMANS**, Department of Biology, La Sierra University, Riverside, California 92515-8247,USA.

TESTUDINES

GRAPTEMYS PSEUDOGEOGRAPHICA (False Map Turtle). USA: ILLINOIS: Rock Island Co: Moline. (90°30.00'N, 41°25.00'W). Sec. 13 R1W T17N. 25 June 1956. Donald Richards. HDW-NIU 1801 (formerly RE 074 in the Putnam Mus. Hist. and Nat. Sci., Davenport, Iowa). Verified by Christine Chandler. New county record for Rock Island County, and extends the range 235 km N of the nearest western locality reported by Phillips et al.

(1999. Field Guide to Amphibians and Reptiles of Illinois, Illinois Nat. Hist. Surv. Manual 8. 282 pp.).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

CROCODYLIA

ALLIGATOR MISSISSIPIENSIS (American Alligator). USA: TEXAS: Morris Co: 2.2 km E US 259 and 1.1 km S FM 250 off Upper Dam Road. 26 May 2002. L. Hampton. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26995, photographic voucher). Verified by Stanley E. Trauth. New county record (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp.). Specimen was estimated to measure ca. 3 m in total length. Circa 1977, another specimen was observed at a nearby site in Morris County at Lone Star Lake (Ellison Creek Reservoir). Lone Star Steel Company erected a statue to it but no voucher or photograph was ever obtained.

Submitted by **CHRIS T. McALLISTER** and **BEVERLY K. ALLEN**, Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA (e-mail: chris.mcallister@tamut.edu).

LACERTILIA

ANOLIS PORCATUS (Cuban Green Anole). DOMINICAN REPUBLIC: DISTRITO NACIONAL: Boca Chica, grounds of the Hotel Coral Hamaca (18°26.919'N, 69°36.323'W). 4 January 2002. Matthew E. Gifford. Verified by Robert Powell. Bobby Witcher Memorial Collection, Avila College (BWMC 06827). This female specimen represents the first record for Boca Chica and extends the known range ca. 10 km E of the nearest previously known locality at the Aeropuerto de las American (Powell 1992. Cat. Amer. Amphib. Rep. 541:1–5; Powell and Parmerlee 1991. Herpetol. Rev. 22:65). *Anolis porcatus* has apparently displaced the Hispaniolan endemic, *A. chlorocyanus*, throughout Santo Domingo and appears to be doing the same in Boca Chica. We saw only *A. porcatus* south of the main east–west highway through Boca Chica, even though *A. chlorocyanus* was common as recently as the summer of 2001. Only one *A. chlorocyanus* was seen in the city in 2002, but it was north of the highway.

Submitted by **MATTHEW E. GIFFORD** (e-mail: gif3@hotmail.com) and **BRIAN E. FONTENOT**, Department of Biology, University of Texas at Tyler, Tyler, Texas 75799, USA, and **DAVID M. NIEVES**, Reptile Education and Research, 8816 North Charlotte, Kansas City, Missouri 64155, USA.

ASACCUS ELISAE (Werner's Leaf-toed Gecko). TURKEY: SANLIURFA PROVINCE: Harran Village (36°51'N, 38°59'E). 20 April 2000. W. Bischoff, M. Franzen, and J. F. Schmidtler. Verified by W. Böhme. Three specimens (one male ZFMK 75849, one female ZFMK 75850, and one in Schmidtler's private collection) were collected from under wall carpets in the Trulli House Museum. Another individual was observed in a tree on the roof of a house at the ancient citadel. These specimens represent the second record in Turkey, extending the distribution ca. 90 km ESE from the Euphrates Valley at Birecik onto the Mesopotamian Plain (Baran and Gruber 1982. Spixiana 5:109–138; Böhme 1973. Bonn. Zool. Beitr. 24:394–398; Tok et al. 1997. Israel J. Zool. 43:71–77). Only two additional records have been reported from the Euphrates Valley in adjoining eastern Syria (Martens and Kock 1991. Senckenbergiana Biol. 71:15–21). Martens and Kock (*op. cit.*) predicted an anthropogenic range extension of this rock-dwelling species along rivers of the Mesopotamian Plain. Our finding supports this prediction because the present sampling site is located within an ancient settlement near a small river (Gülabdere or Al 'Balikh, a tributary of the Euphrates).

CNEMIDOPHORUS NATIVO (NCN). BRAZIL: BAHIA: Camamu Municipality: Ilha Grande (13°55'17"S; 39°00'32"W). 27 October 1999. J. A. P. Schineider and G. I. de Almeida. Museu Nacional, Rio de Janeiro (MNRJ 9487–9). Verified by M. Soares. Northernmost record for the species. Extends distribution ca. 415 km N of previous northernmost locality, in Cumuruxatiba District (17°05'S; 39°10'W), Prado municipality, also in the state of Bahia (Rocha et al. 1999. Herpetol. Rev. 30:109), and ca. 600 km N from type locality in Linhares municipality, state of Espírito Santo. With this new record, the species is now known from six localities along the coast of Espírito Santo (Linhares, Conceição da Barra, and Itaúnas municipalities) and Bahia (Nova Viçosa, Prado, and Camamu municipalities). We thank the Conselho Nacional do Desenvolvimento Científico e Tecnológico (CNPq, processes 300819–4 and 461970/00–7) for funding.

CNEMIDOPHORUS NEOMEXICANUS (= ***ASPIDOSCELIS NEOMEXICANA***) [Reeder et al. 2002. Am. Mus. Novit. 3365:1–61]. (New Mexico Whiptail). USA: NEW MEXICO: De Baca Co: Fort Sumner, northwest section of De Baca County Landfill (east to the end of Landing Road from 17th Street, N of U.S. Hwy 60-84 (34°28.827'N, 104°13.385'W), 1263 m elev. 9 June 2002. Harry L. Taylor. University of New Mexico Museum of Southwestern Biology (MSB 65617). Verified by Charles W. Painter. First record for De Baca County and the Pecos River Drainage (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, 431 pp.). The only other population of *C. neomexicanus* reported from eastern New Mexico is located in the vicinity of Conchas Lake, San Miguel County (Leuck et al. 1981. Southwest. Nat. 26:72–74). There are two competing hypotheses to explain the striking geographic disjunction of the Conchas Lake population. The

hypothesis presented with its discovery posited that it probably originated from human introduction. This interpretation was supported by (1) the distance and sub-optimal habitats between the Conchas Lake population and the nearest neighboring populations (in the northern Rio Grande Drainage), and (2) its morphological resemblance to even more distant populations in the southern Rio Grande Drainage. A recent report of *C. neomexicanus* in Arizona (Persons and Wright 1999. Herpetol. Rev. 30:207–209) demonstrates the capacity of this species to establish a population after an apparent introduction far removed from its principal range. However, the population of *C. neomexicanus* at Fort Sumner provides greater support to the alternate hypothesis (Walker et al. 1992. Southwest. Nat. 37:82–86) that the Conchas Lake population was established after natural dispersal. The linear distance between the populations at Conchas Lake and Fort Sumner is only 100 km, and suitable habitat in the intervening area enhances the chance that other populations may occur there.

EUMECES SEPTENTRIONALIS OBTUSIROSTRIS (Southern Prairie Skink). USA: OKLAHOMA: Choctaw Co: off U.S. 70, near jct. Oklahoma 209, vic. Fort Towson. 18 April 2002. Joshua E. Kessler. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26661). Verified by Stanley E. Trauth. New county record and extends range eastward from adjacent Bryan County into a hiatus in the southeastern part of the state (Secor and Carpenter 1984. Oklahoma Herpetol. Soc. Spec. Publ. 1:1–57; Webb 1970. Reptiles of Oklahoma. Univ. Oklahoma Press, Norman, Oklahoma, 370 pp.; Oklahoma Biological Survey's Distribution of Oklahoma Amphibians and Reptiles by Recorded Sightings, DOKARRS [http://www.biosurvey.ou.edu/dokadesc.html]). The species is also found across the Red River in extreme northern Texas in nearby Red River County (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, 421 pp.). Specimen found among railroad crossties with *Ambystoma texanum*, *Elaphe obsoleta lindheimerii*, and *Tantilla gracilis*.

Submitted by **CHRIS T. McALLISTER** and **JOSHUA E. KESSLER**, Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA (e-mail [CTM]: chris.mcallister@tamut.edu).

HEMIDACTYLUS MABOUIA (Amerafrican House Gecko). USA: FLORIDA: Charlotte Co: 25001 Burnt Store Road (26°47'11"N, 82°02'15"W). 4 October 2001. Florida Museum of Natural History (UF 131752); Lee Co: 2 localities: N. Ft. Myers, 14487 North Cleveland, South Trust Bank (26°40'27"N, 81°53'51"W). 29 May 2001. UF 131745–9; and Bonita Springs, 24181 Hwy 41, Truly Nolen Pest Prevention. 30 May 2001. UF 131755. Collected by Gregg S. Klowden. All verified by Kenneth L. Krysko. New county record for Charlotte County. First mainland, but not county, record for Lee County. This species was previously reported on the Gulf Coast in Monroe County (Butterfield et al. 1993. Herpetol. Rev. 24:111–112), Collier County (Bartlett and Bartlett. 1999. A Field Guide to Florida Reptiles and Amphibians. Gulf Publishing Co., Houston, Texas), and on Gasparilla Island in Lee County (Townsend et al. 2002. Herpetol. Rev. 33:75). The northern and southern Lee County records reported here, as well as additional observations, indicate that this species is well established throughout Lee County. Charlotte record represents the northernmost record on the Gulf Coast of Florida. Specimens of various size classes have also been observed slightly farther north within the center of Charlotte County indicating that this species is well established. *H. mabouia* will likely continue to move north along the Gulf Coast as it has on Florida's Atlantic coast (Butterfield et al. 2000. Herpetol. Rev. 31:53; Criscione et al. 1998. Herpetol. Rev. 29:248).

HEMIDACTYLUS PALAICHTHUS (House Gecko). VENEZUELA: GUARICO: carretera Universidad Rómulo Gallegos-El Castrero, sede Bomberos Universitarios, San Juan de los Morros, 500 m elev. Gilson Rivas. 19 January 2002. Museo de Historia Natural La Salle, Caracas (MHNLS 15571, adult female with two enlarged eggs). Verified by C. Molina. First state record and easternmost locality in the Venezuelan Coastal Range (Serranía del Interior). Extends the known distribution in this coastal area ca. 500 km to the southwest from the easternmost Península de Paria (Kluge 1969. Misc. Publ. Mus. Zool. Univ. Michigan 138:1–78; Powell 1990. Cat. Amer. Amph. Rept. 468.1). This taxon was previously known in Venezuela from the Venezuelan Guayana (Kluge, *op. cit.;* Rivas and Molina, in press. Herpetol. Rev.), the Venezuelan lowland region of Los Llanos (Staton and Dixon 1977. J. Herpetol. 11:17–24; Kornacker 2001. Herpetol. Rev. 32:119),

and the Andean piedmont (lowland versants of the Cordillera de Mérida) (Markezich 2002. Herpetol. Rev. in press). The presence of *H. palaichthus* in Anzoátegui (Kornacker, *op. cit.*) and Delta Amacuro (Rivas and Molina, *op. cit.*) supports the contention that these northeastern Venezuelan states, along with Sucre and Monagas, form a natural biogeographical "corridor" to the Amazonian herpetofauna.

LACERTA BILINEATA (Western Green Lizard). USA: KANSAS: SHAWNEE CO: Topeka. A species of *Lacerta* was introduced to urban SW Topeka in the late 1950s where it established a population confined to a few blocks around Gage Blvd and 21st Street, and was described as *L. viridis* (cf. Behler and King 1979. The Audubon Society Field Guide to North American Reptiles and Amphibians. A. A. Knopf, New York, 719 pp.). Based on hybridization experiments (Rykena 1991. Mitt. Zool. Mus. Berlin 67:55–68) and on genetic distance measured over 17 allozyme loci (Amann et al. 1997. Salamandra 33:255–268), *L. viridis* was later split into the green lizard (*L. viridis*) and western green lizard (*L. bilineata*). The only suitable character to distinguish these similar-looking sister species in the field is the coloration of hatchlings, which is brown dorsally and laterally, and yellowish ventrally in *L. viridis*. Young *L. bilineata* look similar but have green throats, and sometimes also green flanks (Rykena, *op. cit.*; Amann et al., *op. cit.*; Deichsel and Miller 2000. Kansas Herpetol. Soc. Newsl. 119:10–11). Deichsel and Miller (*op. cit.*) concluded that the Topeka population is *L. bilineata* based on morphological examination of 10 juveniles. Here, we confirm this conclusion using a molecular approach.

We analyzed blood drawn from the vena caudalis of three adults: two males kept by James Gubanyi (Topeka) from his garden and a female caught in another garden about 200 m away, where it was subsequently released. Total DNA was extracted from blood following standard proteinase K and phenol chloroform protocols (Sambrook et al. 1989. Molecular Cloning: A Laboratory Manual. Cold Springs Harbor Laboratory Press, Cold Springs Harbor, New York). A 1140 bp fragment of mtDNA containing the cytochrome b gene was amplified by PCR (for primer sequences and PCR conditions see Kalyabina et al. 2001. Russian J. Herpetol. 8:149–158) and sequenced using automatic capillary sequencer (ABI 3100). A part of the cyt b gene consisting of 718 bp was used for analysis. Sequences were deposited at GenBank/NCBI (Accession Nos. AY099282, AY099283, AY099284). According to the cytochrome b sequences, the three samples examined appear identical. To verify the species status of these individuals, their sequences were compared to four reference sequences, two of which were retrieved from *L. viridis* (Slovenia and northern Turkey) and two from *L. bilineata* (Boppart, Germany). Genetic distance between *L. bilineata* and the Topeka samples was 0.3% (2 substitutions). In contrast, the differences between the Topeka samples and *L. viridis* were significantly higher (7%, averaging 47 substitutions). Additionally, sequences of the Topeka samples were compared to the database HUSAR (Heidelberg Unix Sequence Analysis Resources) and a 100% match to *L. bilineata* was found, confirming that the samples represent that species.

Submitted by **SVETLANA A. KALYABINA-HAUF***, Department of Herpetology, Zoological Institute RAS, Universitetskaya emb. 1, St. Petersburg, Russia 199034; and

GUNTRAM DEICHSEL, Friedr.-Ebert-Str. 62, Biberach an der Riss, Germany D-88400. *Present address (SAK): Institute of Pharmaceutical Biology, Ruprecht-Karls-Universität, INF 364, Heidelberg, Germany D-69120 (e-mail: kalyabina@hotmail.com); (e-mail [GD]: Guntram.Deichsel@bc.boehringer-ingelheim.com).

LIOLAEMUS CHILIENSIS (NCN). CHILE: REGION IX: Victoria (38°20'S, 72°15'W), 26 December 2001 (MZUC 26645–46) and Curacautín (38°26'S, 71°53'W), 28 December 2001 (MZUC 26647–48). Region X: Lanco (39°27'S, 72°47'W), 28 December 2001 (MZUC 26649). Museo de Zoología, Universidad de Concepción. R. Moreno, M. Vidal, M. Fernández, and R. Cifuentes. Verified by P. Victoriano. This species occurs in areas ranging from Mediterranean to Temperate Southern Chilean forests and the Patagonia (Neuquén, Argentina). Hellmich (1938. Zoologischer Anzeiger 124[9–10]:237–249) established Villarrica Lake as the southernmost limit of this species. Later, Codoceo (1954. Investigaciones Zoológicas Chilenas 2[5]:69–71) stated that the area surrounding Lake Enco (Region X) was the southern range limit. Donoso-Barros (1966. Reptiles de Chile. Ediciones de la Universidad de Chile. 458 pp.) indicated that the range of this species extended to the north of Valdivia in the Lakes Region. This distribution is supported by Cei (1986. Reptiles del Centro, Centro-oeste y Sur de la Argentina. Herpetofauna de las Zonas Áridas y Semi-áridas. Museo Regionale di Scienze Naturali Torino. 527 pp.). However, Veloso and Navarro (1988. Boll. Mus. reg. Sci. nat. Torino 6[2]:481–539) suggest a more limited distribution in Chile; from Coquimbo (30°10'S; 71°15'W) to the Bío-Bío Region (37°45'S; 72°00'W). These new specimens support Donoso-Barros (1966, *op. cit.*) and Cei (1986, *op. cit*) and confirm the presence of the species in Region X, Región de los Lagos.

CHIRONIUS QUADRICARINATUS MACULOVENTRIS (Cobra Cipo, Sacaiboia). BOLIVIA: DEPARTAMENTO TARIJA: Villa Montes: 63°30'W, 21°15'S. 440 m elev. February 1986. H. Meier. Verified by Wolfgang Böhme. Museum Alexander Koenig, Bonn, Germany (ZFMK 46356). *Chironius quadricarinatus maculoventris* is a large lowland snake known from the Chaco forests in northeastern Argentina and western Paraguay (Dixon et al. 1993. Revision of the Neotropical Snake Genus *Chironius* Fitzinger [Serpentes, Colubridae]. Monografie XIII, Museo Regionale di Scienze Naturali, Torino, 279 pp.). This specimen, from Chacoan forests of southern Bolivia, represents the first record from that country. The voucher specimen is a male with a total length of 1195 mm (tail length 392 mm) and is the largest specimen of this subspecies known.

CORONELLA AUSTRIACA (Smooth Snake). SWEDEN: STOCKHOLM ARCHIPELAGO: Grinda (UTM: 362000E, 6588000N). 27 May 1999. Åsa Claesson and Christopher O'Brien. Verified by Richard Franz. Voucher material (color slide) deposited at Florida Museum of Natural History (UF 132738). The specimen was captured while outstretched on leaf litter at a rocky edge of a forest stand. This is the first record for the small island of Grinda. Of the three species of snakes in Sweden, *C. austriaca* has a spotty distribution (Ahlén et al. 1995. Sveriges Grodor, Ödlor och Ormar. Naturskyddföreningen, Stockholm). The specimen was photographed and released on site.

Submitted by **CHRISTOPHER O'BRIEN**, 2829 SW 39th Avenue, Gainesville, Florida 32608, USA; e-mail: mailcob@ufl.edu.

CROTALUS HORRIDUS (Timber Rattlesnake). USA: TEXAS: Bastrop Co: Griffith League Ranch, a 5000-acre site owned by the Capitol Area Council of the Boy Scouts of America (30°12'52"N, 97°13'58"W). 18 May 2002. Lee Ahlbrandt, Kensley Jones, Michael Forstner. University of Texas Arlington (UTA Slide No. 26921). Verified by Kathryn Vaughn. Specimen collected from a trap in a herpetofaunal array; first record from the county (Dixon 2000. Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.) This record bridges a gap in the distribution of the species between Lee County to the northeast and Caldwell County to the southwest.

Submitted by **LEE AHLBRANDT** (e–mail: ta49816@swt.edu), **KENSLEY JONES,** and **MICHAEL FORSTNER**, Department of Biology, Southwest Texas State University, San Marcos, Texas 78666, USA.

ELAPHE GUTTATA GUTTATA (Cornsnake). USA: FLORIDA: Gadsden Co: Concord, Co. Rd 157, DOR 0.6 km S of intersection with Co. Rd 12 (30°38.089'N, 84°21.796'W). 7 May 2002. Matthew J. Aresco. Verified by K. L. Krysko. UF 132471. New county record.

Submitted by **MATTHEW J. ARESCO**, Department of Biological Science, Florida State University, Tallahassee, Florida 32306-1100, USA; e-mail: aresco@bio.fsu.edu.

GLOYDIUS BLOMHOFII BREVICAUDUS (Mamushi). CHINA: GUANGDONG PROVINCE: Nan Ao Island: Xia Shi Shan. Two male snakes were presented to James Lazell by Yei De Fu on 29 June 2000. Both specimens were initially deposited with Professor Li Zhenchang at South China Normal University, Guangzhou, Guangdong, Peoples Republic of China. One of them, YPM field number AA 4650 remains there but the second, cataloged as YPM 9828 (field number AA 4649), was exchanged to Yale Peabody Museum of Natural History. Identification verified by M. Shpak. This is a first record for Guangdong Province (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. SSAR. 614 pp.) as well as a new record for the island of Nan Ao (Lazell et al. 1999. Postilla 217:1–18). This extends the known range by ca. 400 km from northwest Fukien Province (Ding and Zheng 1974. Publ. Dept. Biol. Fujian Normal Univ. [6]:1–93, 37 pls.), and is the southernmost record (Wu et al. 1985. Reptilian Fauna of Guizhou. People's Press, Guiyang, China. I–iv+436 pp.), though Gloyd and Conant (*op. cit.*) referred these populations to *Gloydius blomhofii siniticus* which is now regarded as a junior synonym of *Gloydius blomhofii brevicaudus* (e.g., David and Ineich 1999. Dumerilia. 3:1–500). This disjunct distribution pattern corresponds to that of the lizard *Gekko subpalmatus* (Lazell et al., *op. cit.*).

Submitted by **GREGORY J. WATKINS-COLWELL** (e-mail: gregory.watkins-colwell@yale.edu) and **TWAN A. A. M. LEENDERS** (e-mail: twanleenders@scinax.com), Division of Vertebrate Zoology, Yale Peabody Museum of Natural History, 170 Whitney Avenue, P.O. Box 208118, New Haven, Connecticut 06520, USA.

HYDRODYNASTES BICINCTUS SCHULTZI (Water Snake). BRAZIL: GOIÁS: Municipality of Minaçu, right bank (east) of Tocantins River (13°26'03"S, 48°08'38"W) at Cana Brava region. 18 February 2002. I. Júnior Tonial. Centro de Estudos e Pesquisas Biológicas, Goiânia – GO (CEPB/CB 12.249), collected in Cerrado vegetation. Verified by H. L. R. Silva. This species is previously known from southeastern Brazil, in the State of São Paulo, and in Central Brazil in Brasilia D.F. (Cunha and Nascimento 1978. Mus. Par. Emílio Goeldi Publ. Avulsas n° 51, Belém. 218 pp.; Hoge et al. 1974. Mem. Int. But. 38:167–178.; Jorge da Silva and Sites 1994. Cons. Biol. 9[4]:873–901.; Peters et al. 1970. The Catalogue of Neotropical Squamata, Part I (revised ed. 1986), Smithsonian Institution, 293 pp.). This is the northernmost record for *H. bicinctus schultzi*, extending its geographic distribution ca. 240 km east (Jorge da Silva and Sites, *op. cit.*).

Submitted by **NELSON JORGE DA SILVA JR.** and **IVAN FRANÇA E SOUZA**, Laboratório de Herpetologia, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás, Ave. Universitária, 1440, Setor Universitário, 74210-010, Goiânia, Goiás, Brazil (e-mail: njsj@ucg.br).

LEPTOPHIS AHAETULLA (Parrot Snake). BRAZIL: GOIÁS: Municipality of Minaçu, right bank (E) of Tocantins River (13°26'31"S, 48°08'45"W) at Cana Brava region. 12 February 2002. C. Amaral Souza. Centro de Estudos e Pesquisas Biológicas, Goiânia – GO (CEPB/CB 7511, SVL = 781 mm). Verified by H. L. R. Silva. Although most reports place *L. ahaetulla* in rainforest formations, in Brazil this species has been reported from outside the Amazon rainforest in Mato Grosso (Amaral 1994, Brazilian Snakes: A Color Iconography. 2nd ed. [1978], Univ. de São Paulo Ed., 246 pp.); Mato Grosso do Sul, São Paulo (Cei 1993. Mus. Reg. Sci. Nat. Torino [Monog. XIV], 949 pp.); Tocantins next to Lageado Falls (unpubl. data); and Bahía, in the Caatinga vegetational domain (Amaral, *op. cit.*; Jorge da Silva 1999. Abstr. 42nd Annual Meeting of SSAR, pp. 88–89). Here we provide a new state record for *L. ahaetulla* from a gallery forest within the Cerrado vegetational formation.

This record suggests that this species has a wider distribution in central Brazil than was previously believed (Cei, *op. cit.*; Jorge da Silva and Sites 1994. Cons. Biol. 9[4]:873–901).

Submitted by **IVAN FRANÇA E SOUZA** and **NELSON JORGE DA SILVA JR.**, Laboratório de Herpetologia, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás,

Ave. Universitária, 1440, Setor Universitário, 74210-010, Goiânia, Goiás, Brazil (e-mail: souzai@terra.com.br).

LEPTOTYPHLOPS KOPPESI (Blind Snake). BRAZIL: GOIÁS: Municipality of Minaçu, left bank (W) of Tocantins River (13°26'35"S, 48°08'42"W) at Cana Brava region. 14 February 2002. I. França e Souza. Centro de Estudos e Pesquisas Biológicas, Goiânia - GO (CEPB/CB 8873). Verified by H. L. R. Silva. This is the northernmost record for this species from the Cerrado vegetational domain and a range extension of about 670 km NE and 330 km NW of previously recorded limits (McDiarmid et al. 1999. Snake Species of the World: A Taxonomic and Geographic Reference. Vol. 1. The Herpetologists' League, Washington D.C., 511 pp.; Valdujo and Nogueira 2001. Herptol. Rev. 32:128–130; Nogueira 2001. Herptol. Rev. 32:285–287).

Submitted by **IVAN FRANÇA E SOUZA** and **NELSON JORGE DA SILVA JR.**, Laboratório de Herpetologia, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás, Ave. Universitária, 1440, Setor Universitário, 74210-010, Goiânia, Goiás, Brazil (e-mail: souzai@terra.com.br).

LIOPHIS FRENATUS (False Coral Water Snake). ARGENTINA: CORRIENTES: Santo Tomé Department, ca. 7.3 km N Gobernador Ingeniero Valentín Virasoro town, by National Road N° 14, (27°59'S, 56°01'W). 28 January 2002. V. Arzamendia and A. R. Giraudo. National Institute of Limnology, Santa Fe province (INALI 1048, adult female, 532 mm SVL, 100 mm TL, 37 g body mass). Verified by G. Scrocchi. First province record and third record from Argentina. Establishes the southernmost locality for the species (Dixon 1983. J. Herpetol. 17:149–165). Extends range ca.75 km S of the nearest populations in Posadas, Misiones, Argentina (Giraudo 1999. Herpetol. Rev. 30:179) and 83 km S of the Paraguayan Paraná Islands, flooded by the closing of Yacyretá Dam, Itapúa, Paraguay (Alvarez et al. 1995. Facena 11:69; Aquino et al. 1996. *In* Martinez [ed.], Colecciones de Flora y Fauna del Mus. Nac. Hist. Nat. Paraguay, Asunción, pp. 332–400).

Submitted by **VANESA ARZAMENDIA** and **ALEJANDRO R. GIRAUDO**, Instituto Nacional de Limnologia, Consejo de Investigaciones Científicas y Técnicas, José Macia 1933, 3016 Santo Tomé, Santa Fe, Argentina (e-mail [ARG]: alegiraudo@arnet.com.ar).

LIOPHIS MILIARIS MILIARIS (NCN). BRAZIL: PARÁ: Municipio de Oriximiná (55°52'W 01°45'S): Porto Trombetas. J. F. de Carvalho. 1999. Linha de Pesquisa em Herpetologia da Amazônia (LPHA), Laboratório de Pesquisas Zoológicas (LPZ), Faculdades Integradas do Tapajós, Santarém, Pará State (LPHA 1637). Verified by A. G. Guedes. Species known from northern South America in Guiana, Surinam, and French Guiana (Cayenne) (Dixon 1983. Copeia 1983:791–802). The species also occurs in Amapá State, Brazil (Cunha and Nascimento 1993. Bol. Mus. Para. Emílio Goeldi, Sér. Zool. 9[1]:1–191). First state record, enlarges the known distribution ca. 480 km from the nearest record (Serra do Navio) in Amapá State.

Submitted by **ALFREDO PEDROSO DOS SANTOS-JR** and **RUBENS NOBUO YUKI**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200 (e-mail: alphredojr@mailbr.com.br).

MICRURUS PSYCHES (Northern Coral Snake) VENEZUELA: BOLIVAR: Cerro Guaiquinima, west Aberaima River Canyon, 05°46'59"N, 63°47'07"W, 1300 m elev. 28 March 2000. J. Pérez-Emán, C. J. Sharpe, G. Picón, and I. Carreño. Verified by Gilson Rivas. Museo de Historia Natural La Salle (MHNLS 14815). This report constitutes the first specimen of this species collected at this elevation and in the Pantepui Province (Huber 1987. Pantepui [2]:2–10). The species previously has been reported only from forests in southeastern Venezuela, at elevations from 50 m to ca. 500 m (Roze 1996. Coral Snakes of the Americas: Biology, Identification, and Venoms, Krieger Publ., Malabar, Florida. 328 pp.). This specimen was collected in a *Stegolepis* meadow ca. 100 m from a small stream.

Submitted by **CÉSAR MOLINA**, Museo de Historia Natural La Salle, Sección de Herpetología, Apartado Postal 1930, Caracas 1010–A, Venezuela (e-mail: washaema@hotmail.com); **JORGE PÉREZ-EMÁN**, Instituto de Zoología Tropical, Universidad Central de Venezuela, Apartado Postal 47058, Caracas 1041-A, Venezuela (e–mail: jlperez@strix.ciens.ucv.ve); and **CHRISTOPHER J. SHARPE**, Apartado Postal 62826, Caracas 1060, Venezuela (e–mail: net.ve" rodsha@telcel.net.ve).

NERODIA FASCIATA (Southern Watersnake). CORRECTION OF SPECIES IDENTIFICATION: ***NERODIA SIPEDON PLEURALIS*** (Midland Watersnake). USA: FLORIDA: Liberty Co.: Sweetwater Creek (30°30'N; 84°54'W). 7 April 2001. Collected by F. Wayne King. UF 123361. Re-verified by P. E. Moler. This note serves to correct the identification of a specimen previously reported as *N. sipedon pleuralis* (Townsend and King 2001. Herpetol. Rev. 32:196) that has subsequently been identified as *N. fasciata*. This specimen does not represent a new distributional record as *N. fasciata* has previously been documented in Liberty County (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Second Ed. Windward Publ., Miami, Florida. 176 pp.).

Submitted by **JOSIAH H. TOWNSEND**, Division of Herpetology, Florida Museum of Natural History, Gainesville, Florida 32611, USA.

OPHEODRYS AESTIVUS (Rough Greensnake). USA: TEXAS: Marion Co: 11.3 km NW Jefferson off FM 728 on Kellyville Road 1 at Berea Community. 13 June 2002. Dawn and Miroslav Moore. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 27111). Verified by Stanley E. Trauth. First record for county and partially fills a hiatus in NE Texas (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 421 pp.; Werler and Dixon 2000. Texas Snakes: Identification, Distribution, and Natural History. Univ. of Texas Press, Austin. 437 pp.). Also reported previously from nearby Caddo Lake watershed (Hardy 1995. LSU in Shreveport, Bull. Mus. Life Sci. 10:1–31) and adjacent Caddo Parish, Louisiana (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. LSU Press, Baton Rouge. 300 pp.).

Submitted by **CHRIS T. McALLISTER** and **DAWN I. MOORE,** Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA (e–mail: chris.mcallister@tamut.edu).

PHILODRYAS AESTIVUS (Common Green Racer): BRAZIL: BAHIA: Municipality of Rio de Contas, Brejo farm (13°26'S, 41°50'W). 1500 m elev. 1 April 2000–25 May 2001. Collector unknown. Museu de Zoologia da Universidade Estadual de Santa Cruz (MZUESC 1181); 26 May–21 November 2001. Collector unknown. MZUESC 2103–04. All specimens were found in "campo rupestre" areas. Specimens were captured by different collectors and the precise dates of capture are unknown. Thus, dates indicate periods between visits to the farms. All verified by Miguel Trefaut Rodrigues. Species is known from southwestern and southern Brazil, Amazonian Bolivia, Paraguay, Uruguay, and northern Argentina (Peters and Orejas-Miranda 1970. Bull. U.S. Nat. Mus. 297:241). In Brazil, the northern range limit is the state of Minas Gerais (Barrio et al. 1977. J. Herpetol. 11:230–231). There is a record of *P. aestivus* from Bahia (Johnson 1952. Copeia 1952:283–284), but according to Barrio et al. (*op. cit.*) that specimen was a misidentified *P. olfersii*. These first records from northeastern Brazil extend the species' range 170 km north.

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO,** Universidade Estadual de Santa Cruz - UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil (e-mail: lachesis@uesc.br), and **MARCO ANTÔNIO DE FREITAS,** Rua E quadra D lote 11, Jardim Aeroporto, CEP 42700-000, Lauro de Freitas, Bahia, Brazil (e-mail: philodryas@hotmail.com).

New County Records of Amphibians and Reptiles from Texas

ROBERT W. BRYSON, JR.
and
JAMES M. MUELLER
Department of Biology, Sul Ross State University
Alpine, Texas 79830, USA
e-mail: jmueller@sulross.edu

A recent search of the collection databases in the James F. Scudday Vertebrate Collection at Sul Ross State University revealed eleven new county records of amphibians and reptiles for the state of Texas (Dixon 2000). All specimens were verified by James F. Scudday. Nomenclature follows Dixon (*op. cit.*).

The James F. Scudday Vertebrate Collection at Sul Ross State University contains more than 7500 amphibian and reptile specimens with the Trans-Pecos region of Texas being especially well represented. Most specimens were collected after 1960 by James F. Scudday and his students. A list of holdings is available by contacting JMM.

Caudata

Ambystoma tigrinum mavortium (Barred Tiger Salamander). PECOS CO: 17 mi W Sanderson on Mansfield Ranch. 10 May 1964. Charles Stavley. SRSU A–256. Fills a gap in the documented range of the species in the Trans-Pecos of Texas.

Siren texana (Rio Grande Lesser Siren). WILLACY CO: Farm ponds. 30 March 1970. D. Miller and P. Mooney. SRSU A–406, 407, 408. Fills a gap in the documented range of the species along the Texas coast. This species is listed as threatened by Texas Parks and Wildlife Department. Dixon (2000:51–52) described the uncertainty regarding the taxonomy of sirens in this region.

Anura

Bufo cognatus (Great Plains Toad). Loving Co: Kyle Ranch, 16 mi N of Orla; 3 mi E off Co. Rd. 652. 8 June 1995. J. Hamilton. SRSU A–1498. Extends the range of the species to the edge of the Sand Hills of the Trans-Pecos.

Syrrhophus (=Eleutherodactylus) guttilatus (Spotted Chirping Frog). JEFF DAVIS CO: 8.4 mi N of Hwy 90 on Hwy 118. 25 July 1990. John Hollister. SRSU A–1331, 1332, 1333. Extends the range of the species to include the Davis Mountains and confirms an observation of calling reported by King (Dixon 2000:64).

Testudines

Sternotherus odoratus (Stinkpot). REAL CO: East Prong of the Nueces River, Eagle Nest Ranch. 7 November 2001. James Mueller. SRSU R–6571. Fills a gap along the western edge of the documented range in Texas.

Trachemys scripta elegans (Red-eared Slider). PECOS CO: Co. Rd. 2593 between Pecos River and Imperial Reservoir; 7 mi S Grand Falls. 17 October 1989. Steve Gibson. SRSU R–5995. Same locality. 22 October 1989. Steve Gibson. SRSU R-5996.

Lacertilia

Anolis carolinensis (Green Anole). LIVE OAK CO: NE side of Lake Corpus Christi. 7 February 1987. Donna Quillian. SRSU R–5876, 5903, 5904. Fills a gap along the western edge of the species' range in south Texas. The documented range of this species in Texas is rapidly expanding, possibly due to accidental introductions (Dixon 2000:107).

Eumeces obsoletus (Great Plains Skink). LOVING CO: E side of Red Bluff Lake. 26 June 1986. Ellie Springfield. SRSU R–5689.

Sceloporus undulatus consobrinus (Southern Prairie Lizard). BORDON CO: Lake J. B. Thomas. 20 February 1966. Culligan. SRSU R–731.

Serpentes

Coluber constrictor flaviventris (Eastern Yellow-bellied Racer). WHEELER CO: E Wheeler, Britt Ranch. 8 February 1992. J. P. Karges. SRSU R–6347.

Diadophis punctatus regalis (Regal Ring-necked Snake). REEVES CO: 4.5 mi NE of Balmorhea. 13 October 1990. Scott McDonald. SRSU R–6047.

Acknowledgments.—We thank J. R. Dixon for verifying that these records are new. We also thank James F. Scudday for reviewing these records, and for his decades of work that are recorded for future generations in the James F. Scudday Vertebrate Collection.

New Herpetological Records for High and Hog Islands of the Beaver Archipelago, Charlevoix County, Michigan

JOHN S. PLACYK JR.
Department of Ecology and Evolutionary Biology
University of Tennessee, 569 Dabney Hall, Knoxville, Tennessee 37996, USA
e-mail: jplacyk@utk.edu

MICHAEL J. SEIDER
Warnell School of Forest Resources
Athens, Georgia 30602, USA

and

JAMES C. GILLINGHAM
Department of Biology, Central Michigan University
Mt. Pleasant, Michigan 48859, USA

The Beaver Archipelago is situated in northeastern Lake Michigan in Charlevoix County, Michigan, USA. The archipelago consists of four main islands: Beaver, Garden, High, and Hog, which range in size from ca. 6.2 km^2 to 93.4 km^2. In addition there are eight smaller islands: Grape, Gull, Hat, Pismire, Shoe, Squaw, Trout, and Whiskey, each $\leq$ 0.64 km^2. Faunal surveys of the archipelago have been limited, with the last summary of such surveys being compiled in Hatt et al. (1948). Most of the early surveys described in Hatt et al. (1948) focused almost exclusively on the avian and mammalian faunas of the archipelago with little information on the amphibians and reptiles. In addition Garden, High, and Hog islands had not been surveyed at the time Hatt et al. (1948) published their book. Since 1948, an extensive survey of the land vertebrates of Garden Island has been conducted (Phillips et al. 1965); however, the land vertebrates of High and Hog islands remained unsurveyed.

While conducting field research on Common Garter Snake (*Thamnophis sirtalis*) populations between May and August 2001, six new herpetofaunal records were obtained from High Island and two from Hog Island. Specimen identifications were verified by Kenneth Bowen or Kerry Hansknecht. Voucher specimens were deposited at the University of Tennessee, Knoxville Reptile Ethology Lab collection (UTKREL).

Caudata

Ambystoma laterale (Blue-spotted Salamander). CHARLEVOIX CO: High Island. Margin of Lake Maria under a log. 17 July 2001. J. S. Placyk, Jr. and M. Seider. UTKREL 01–HI–7001.

Notophthalmus viridescens (Eastern Newt). CHARLEVOIX CO: High Island. Margin of Lake Maria under a log. 9 July 2001. J. S. Placyk, Jr. and M. Seider. UTKREL 01–HI–2001.

Plethodon cinereus (Eastern Red-backed Salamander). CHARLEVOIX CO: High Island. Margin of Lake Maria under a log. 9 July 2001. J.S. Placyk, Jr. UTKREL 01–HI–8001.

Anura

Bufo americanus (American Toad). CHARLEVOIX CO: Hog Island. Along west coast of island. 9 July 2001. J. S. Placyk, Jr. UTKREL 01–HO–0001.

Rana clamitans (Green Frog). CHARLEVOIX CO: High Island. In Lake Maria. 23 June 2001. J. S. Placyk, Jr. and J. C. Gillingham. UTKREL 01–HI–3001.

Serpentes

Nerodia sipedon (Northern Watersnake). CHARLEVOIX CO: High Island. Margin of Lake Maria under a log. 17 July 2001. J. S. Placyk, Jr. and M. Seider. UTKREL 01-HO-5002. Hog Island: West coast of island on beach. 09 July 2001. J. S. Placyk, Jr. and M. Seider. UTKREL 01–HO–5001.

Storeria occipitomaculata (Red-bellied Snake). CHARLEVOIX CO: High Island. Margin of Lake Maria within a log. 9 July 2001. J. S. Placyk, Jr. and M. Seider. UTKREL 01–HI–1001.

Acknowledgments.—All specimens were collected under the provisions of Cultural and Scientific Collectors Permit no. CO 1000 issued to JSP by the Fisheries Division of the Michigan Department of Natural Resources. We thank J. Picotte for his field assistance and R. Mehta for comments on the manuscript.

New Records for Amphibians in the Big South Fork Region of Tennessee

TODD S. CAMPBELL
Institute for Biological Invasions
Department of Ecology and Evolutionary Biology
569 Dabney Hall, University of Tennessee
Knoxville, Tennessee 37996, USA
e-mail: lizardman@utk.edu

Established in 1974 to thwart construction of a reservoir, the Big South Fork National River and Recreation Area (BISO) encompasses ca. 125,000 acres of the Cumberland Plateau and Big South Fork River gorge in southeastern Kentucky and northeastern Tennessee. Past clear-cutting and coal mining operations dramatically altered the Plateau and its waterways, but the area has recovered such that BISO preserves significant regional biota, habitats, and geological features.

Formal herpetofaunal research in the region consists of a single unpublished study in McCreary County, Kentucky (Stephens 1985). In fact, many common Tennessee amphibians exhibit unexplainable holes in their distributions in the counties encompassing BISO (Redmond and Scott 1996). In Summer 2000 and Spring 2001, I set out to determine if these were sampling or publishing artifacts, disturbance-related gaps that filled as forests regenerated, or legitimate distributional discontinuities caused by natural conditions or landscape alterations (Campbell 2002).

I searched for amphibians and reptiles while traveling all the roads and sanctioned trails in BISO (Campbell and Campbell 2002). Here I document 18 county records for 11 species of amphibians in the counties encompassing BISO, based on Redmond and Scott (1996) and subsequent published literature. All specimens were collected and/or photographed by the author and identified using Conant and Collins (1998), Powell et al. (1998), Petranka (1998), and/or Altig (1970). Identifications were verified by A. Floyd Scott and deposited in the Austin Peay State University Museum of Zoology (APSU) in Clarksville, Tennessee.

Caudata

Ambystoma maculatum (Spotted Salamander). FENTRESS CO: Adult crossing TN154 ca. 0.64 km N of its intersection with Divide Road. 12 April 2001. APSU 06167. Fentress County record. MORGAN CO: Two adults found dead-on-road (DOR) on TN52 ca. 0.32 km W of Rugby, Tennesse. 12 April 2001. APSU 06159. Morgan County record. PICKETT CO: One larva in a road puddle in Middle Creek Road 0.48 km E of its intersection with Divide Road in BISO. 2 June 2000. APSU 06140. Adult crossing TN154 ca. 500 m SW of Pickett–Scott County line. 12 April 2001. APSU 06166. Pickett County records. SCOTT CO: Five larvae in a roadside ditch along Duncan Hollow Road ca. 1.6 km N of Bandy Creek Campground in BISO. 29 May 2000. APSU 06136. One small larva in a puddle in Terry Cemetery Road ca. 50 m E of Terry Cemetery in BISO. 2 June 2000. APSU 06138. One larva in a road puddle in Maude's Crack trail ca. 0.64 km W of Maude's Crack in BISO. 2 June 2000. APSU 06139. Two adults found DOR on TN52 ca. 1.45 km E of the Scott–Morgan County line. 12 April 2001. APSU 06158. Scott County records.

Gyrinophilus porphyriticus (Spring Salamander). SCOTT CO: Adult crossing TN154 ca. 100 m N of the Pickett–Scott County line in BISO. 12 April 2001. APSU 06165. Scott County record.

Hemidactylum scutatum (Four-toed Salamander). Scott Co: Adult crossing TN297 ca. 80 m W of the bridge over Bandy Creek in BISO. 12 April 2001. APSU 06162. Scott County record.

Plethodon dorsalis (Northern Zigzag Salamander). FENTRESS CO: Adult guarding egg mass in a narrow crack in a rock wall ca. 0.16 km N of Indian Rock House on Slave Falls Loop in BISO. 30 July 2000. APSU 06151 (specimen and color slide). Fentress County record. SCOTT CO: Adult photographed with egg mass in a crack in a rock wall in a narrow canyon between two overlook spur trails on the John Muir Trail, ca. 4.67 km north of its intersection with Grand Gap Loop in BISO. 10 July 2000. APSU 06171 (color slide). Scott County record.

Pseudotriton ruber (Red Salamander). SCOTT CO: Adult found DOR on TN297 on the east side of the Big South Fork River gorge ca. 0.96 km E of the Leatherwood Ford Bridge in BISO. 12 April 2001. APSU 06153. Scott County record.

Anura

Hyla chrysoscelis (Cope's Gray Tree Frog). SCOTT CO: Adult female found DOR on TN297 on the east side of the Big South Fork River gorge ca. 0.64 km E of the Leatherwood Ford Bridge in BISO. 17 June 2000. APSU 06148. Scott County record.

Pseudacris crucifer (Spring Peeper). MORGAN CO: Three adults crossing TN52 ca. 0.16 km W of Farrington Road near Newberry House Pond in Rugby, Tennessee. 12 April 2001. APSU 06161. Morgan County record.

Pseudacris feriarum (Upland Chorus Frog). FENTRESS CO: 15 tadpoles in a roadside ditch on the south side of Darrow Ridge Road ca. 2.6 km E of its intersection with TN154; the southwestern boundary of BISO. 27 May 2000. APSU 06132. Fentress County record.

Rana palustris (Pickerel Frog). MORGAN CO: Adult found DOR on TN52 ca. 0.16 km W of Farrington Road near Newberry House Pond in Rugby, Tennessee. 12 April 2001. APSU 06154. Morgan County record.

Rana sylvatica (Wood Frog). PICKETT CO: Seven tadpoles in a puddle in Middle Creek Road ca. 0.16 km E of Divide Road in BISO. 2 June 2000. APSU 06137. Pickett County record. SCOTT CO: Four tadpoles in a road puddle on Smith Ridge Road ca. 2.57 km E of its intersection with Duncan Hollow Road in BISO. 28 May 2000. APSU 06131. Two tadpoles in a roadside ditch along Duncan Hollow Road ca. 1.61 km N of Bandy Creek Campground in BISO. 29 May 2000. APSU 06135. Scott County records.

Scaphiopus holbrookii (Eastern Spadefoot). FENTRESS CO: Adult crossing TN52 at the entrance to Brewster Bridge Picnic Area and River Access, ca. 0.48 km W of the Brewster Bridge over Clear Fork in BISO. 12 April 2001. APSU 06160. Fentress County record. PICKETT CO: Two adults in a roadside ditch on the west side of TN154 near the entrance to Pickett State Park Superintendent's Residence ca. 1.93 km N of the Pickett State Park office. 3 June 2000. APSU 06172 (color slide). Pickett County record. SCOTT CO: Nine tadpoles in an ephemeral woodland pond on the east side of Twin Arches Road ca. 1.29 km NW of the Twin Arches Trailhead and ca. 300 m E of the Scott-Pickett County line in BISO. 2 June 2000. APSU 06133. Scott County record.

Acknowledgments.—This work was performed under National Park Service Resource Activity Permit BISO–N–00–01 and Tennessee Wildlife Resources Agency Scientific Collecting Permit 1606-00. Thanks to Reid Detring and Robert Emmott (BISO) for providing logistical support and waiving housing costs as compensation for this survey.

What a lovely book!

Tadpoles of South-eastern Australia is the most comprehensive regional guidebook for tadpoles that I have ever seen. It is quaint in style, yet heroic in scope.

In this beautifully illustrated volume, Marion Anstis manages to describe the tadpoles of 84 of the 89 species of anurans found in the southeastern corner of Australia. The tadpoles for 30 of those species have never been described before. Thus this book introduces an enormous amount of new information on Australian anurans.

However, anyone interested in tadpoles from anywhere in the world should look at this book. Here is why.

In sixteen, heavily-illustrated pages at the beginning of the book, Anstis sorts tadpoles into 17 types, based on body shape, and 15 types, based on oral disc morphology. This classificatory scheme is a major refinement on the more common bipartite sorting of tadpoles into simply pond (lentic) and stream (lotic) forms. Similarly, the otherwise "common" pond tadpole oral disc, with its 2/3 denticle formula, is subdivided here into a half dozen well-defined and well-illustrated categories. With so many precisely defined morphological categories, herpetologists can begin to distinguish coexistent tadpoles of similar habitus from other regions of the world. I invite anyone describing tadpoles in the future to start with Anstis's descriptive categories, modifying them as necessary to meet their local needs.

Furthermore, only when one can see and describe morphological differences can one begin to understand the adaptive significance of those differences. Thus Anstis's partitioning of tadpoles, based on subtle variants in body shape and oral morphology, opens the way to understanding what these variations mean to the locomotor (e.g., Van Buskirk and McCollum 2000) and feeding (e.g., Wassersug and Yamashita 2001) activities of these animals.

Every species account in this book includes a photograph of the adult, a distribution map for the species, an illustration of the tadpole in lateral view, an illustration of the tadpole's oral disc, *and* photographs of the tadpole in both dorsal and lateral view. Most tadpole descriptions published elsewhere rely on either photographs or drawings, but not both. It is great to see both here, as they provide different but complimentary information.

Each species account also includes a description of the adults' breeding site, the eggs/embryos, and of course the tadpoles themselves. The accounts end with a few lines on the behavior and ecology of the tadpoles. The species with the most similar looking tadpoles are mentioned and the most effective characters for discriminating between those similar species are noted.

This book is more than illustrated with excellent pictures—it is decorated with them! All the tadpole drawings within are compiled into a mural of pretty pictures on the endpapers, inside the front and back covers. At first those plates appear to be artistic embellishments. But they are practical, allowing readers to instantly compare tadpoles of the different species, without having to flip through the whole volume.

The book is clearly aimed at the amateur non-herpetologist and does not assume much previous knowledge about the frogs or toads of Australia. All technical terms are defined. Directions are given on how to get permission to collect tadpoles, and then how to raise them and preserve them.

My criticisms are few. As an editorial oversight, in one or two places specialized taxonomic knowledge is presumed of the reader despite the book's targeted audience of neophytes. For example, *Litoria littlejohni* larvae, we are told, are "similar in type to other members of the *L. ewingii* complex" (p. 132). However that complex is never defined. Such slips are minor though. One really doesn't need to know any herpetology to make good use of this book.

I was surprised to read that *Bufo marinus* toadlets are "non-toxic" (p. 29); i.e., not "toxic to predators" (p. 274). Whereas there is good evidence that *Bufo* toxicity varies with developmental stage (see Crossland 1998 and older papers cited therein) and probably among species, given the high toxicity of *Bufo* eggs, tadpoles, and juvenile frogs from around the world, I feel that one should cautiously avoid such sweeping generalizations. Not enough *Bufo marinus* have been tested with enough predators, across the species range (despite Crossland and associates' excellent work in this area; e.g., Crossland and Alford 1998; Crossland and Azevedo-Ramos 1999), to have much confidence in Anstis's claim that their toadlets are palatable. I, for one, am surely *not* about to add *B. marinus* toadlets to my diet.

The parts of the book that are likely to be most difficult to use are the keys, of which there are two: one for eggs/embryos and one for tadpoles. One problem, which is acknowledged by the author, is that the eggs and tadpoles of a few species are not described in this volume. This means that the keys may yield erroneous IDs in some localities, but work flawlessly in others. The problematic species with unknown early life history stages, however, are few and have relatively restricted ranges, which mitigates that problem.

There are two more serious problems related to intraspecific variation, though, that keep this book from being as good as it looks. Although Anstis reports finding two different color morphs for *Litoria dentata* tadpoles at opposite sides of the same pond (p. 114) and regional variation in the color of *Litoria booroolongensis* tadpoles (p. 98), little else is said about natural variation across

species' ranges. Except in a few cases, the tadpoles selected for description and used to develop keys appear to be collected from relatively restricted areas. Thus one cannot help but wonder how well the keys will work or how accurate the descriptions are for wide-ranging species.

The whole topic of phenotypic plasticity—a major thrust of tadpole research for the last decade (see Relyea 2002 and Van Buskirk 2002 for a lead to this literature)—is not mentioned at all in this book. Predator-induced variation in tadpole morphology and behavior is now well documented for many species in North America and Europe, thanks to the work of Andy McCollum, Josh Van Buskirk, Rick Relyea, and their colleagues (discussed in Wassersug 2000). It is also known for tadpoles in Eastern Australia, including ones covered by this book (Peter Kraft and Ed Meyer, pers. comm.). Thus when we are told, for example, that *Cyclorana alboguttata* tadpole "tails are constantly damaged by numerous predators" (p. 86), one might expect those tadpoles to have slightly different shapes, behavior, and possibly color, if raised with and without predators lurking nearby.

I predict that some of the tadpoles described here as fitting one of Anstis's 17 tadpole types will eventually be found to slip into an additional type or two, based on the environment in which they are raised. In sum, phenotypic plasticity is likely to make a bit of a mess of Anstis's otherwise masterful keys. From that mess, however, should emerge a richer understanding of the causes and consequences of intraspecific variation in Australian tadpoles. Hopefully Anstis will incorporate information on that variation into future editions of her book—even if it means that some species may not be confidently diagnosed with the dichotomies provided in a key.

The ranges for many of the species that Anstis discusses are shrinking fast, as humans encroach upon their territory. This is not surprising, for the southeastern corner of Australia is the most populated part of that island continent. Anstis dedicates a whole chapter to the various forces assaulting anuran populations worldwide. In revealing the beauty and diversity of tadpoles, and focusing public attention on the need to protect their habitat, this book is a service to anurans everywhere.

Thus, although it isn't perfect, it is still a darn lovely book.

Most herpetologists now agree that amphibians are declining worldwide. Reports from five continents reveal that population sizes have decreased, entire populations have disappeared, and some species have gone extinct. Within the past decade, the scientific community has rallied together to document these declines and identify the causes.

The Neotropics, home to the world's richest amphibian fauna, has seen some of the most dramatic population declines and thus merits intensive investigation. In November 1999 Karen Lips, Jamie Reaser, Bruce Young, and Roberto Ibáñez held workshops in Mexico, Panama, and Ecuador with the goal of promoting efforts to inventory and monitor amphibians, and of coordinating efforts by investigators in these countries. Prior to the workshops they drafted a monitoring protocol manual and then revised it to reflect input by workshop participants. The National Science Foundation (U.S.) supported publication of the manual, which is now available to all of us.

The authors' stated purpose in writing this manual is "to make guidelines on amphibian monitoring readily available to field workers in Latin America, particularly those who might not have prior experience with amphibian monitoring." Not only have the authors successfully accomplished their goal, they have also produced a manual useful for investigators outside Latin America as well: the guidelines and field methods are appropriate just about anywhere. The authors suggest that investigators interested in initiating amphibian monitoring programs first read this manual for an introduction and guidelines, and then read the Heyer et al. book, *Measuring and Monitoring Biological Diversity: Standard Methods for Amphibians* (1994), for greater depth in field methods and data analysis.

The authors set the stage with a background on amphibian declines, pointing out that we lack the detailed surveys needed to understand patterns of decline, and that only long-term data sets can determine if populations are stable, increasing, or decreasing. Furthermore, we need to examine correlations among population status and environmental variables to identify possible causes of amphibian declines. A table of the biological and socio-economic roles of amphibians, with selected references, will be useful to investigators who need to justify the value of amphibians to the public. A second table—sites of rapid declines in amphibian populations from North America, the Caribbean, Central America, South America, and Australia, with selected references—will introduce the uninitiated to the literature. A third table, with selected references, summarizes the leading hypotheses on factors responsible for amphibian declines.

Next the authors briefly describe ecological monitoring and provide a detailed conceptual framework for establishing amphibian monitoring programs. They emphasize that not everyone will have the resources to undertake sophisticated programs but that even surveys involving a few species are worth the time and effort. This chapter is one of the most important in the book because it offers clear guidelines for developing and implementing a strategic monitoring plan. Particularly useful discussions include (1) identifying specific questions to achieve your goals, (2) how to choose your monitoring targets, (3) how to choose your site, (4) replication and timing of the fieldwork, and (5) which field method to choose.

The third section provides a concise summary of five field methods: visual encounter survey transects, audio transects and surveys at breeding sites, leaf litter plots, larval and egg surveys, and drift fences. A useful table, modified from Heyer et al. (1994), summarizes factors to consider in selecting the most appropriate field methods to obtain specific information. Investigators are urged to follow the DAPTF Fieldwork Code of Practice (provided as an appendix). Additional topics covered include duration and frequency of sampling (you need statistical power to detect changes!) and equipment needed (you don't need much.).

A short section on environmental data collection stresses that weather data are critical because activity and reproductive behavior of amphibians is so closely tied in with climatic variables. A list of standard weather variables and equipment needed to measure these variables includes air and water temperature, precipitation, wind speed and direction, relative humidity, and pH.

The next section is data analysis. Recommendations begin with constructing a species accumulation curve from lists of species present during each survey. One can calculate the number of individuals per area searched (density), the number of individuals per unit of time searched, and then compare transects or habitats. Data on reproductive phenology are valuable for determining optimal times for future monitoring efforts. The authors briefly address the question of major concern: how do we determine whether our focal populations are stable, declining, or increasing? This is a challenging question indeed, since population sizes of many amphibians naturally fluctuate widely from year to year. We may need 10 to 20 years' worth of data to determine if any real change in population size has occurred, ideally using *a priori* power analysis.

Alonso Aguirre and David Green wrote the next section: Analysis of Mortality Causes in Amphibians. What should we do if we find dead or dying amphibians in the field? Here the reader learns what field data to collect to accompany specimens and how to preserve and ship specimens for analysis. The authors warn that because some diseases can be transmitted from amphibians to humans and vice versa we need to take precautions.

A section entitled Other Considerations provides information on research and collecting permits, voucher specimens (including the minimum data that should accompany each specimen), and tape-recorded frog calls as vouchers. The authors emphasize the importance of depositing vouchers and their accompanying data in an institutional collection committed to curating the specimens and making them available for study by other researchers. Advice on personal safety is given as well as ways to avoid spreading infectious diseases among amphibians. Readers are encouraged to communicate their findings with other scientists and with the public.

The list of literature citations includes 65 references. These are certainly not comprehensive, but they should get the reader started. The first of four appendices provides valuable contact information: pathologists who will analyze dead or dying frogs, participants from the NSF-sponsored workshops willing to provide advice concerning monitoring programs, and Latin American herpetological associations. A second appendix suggests possible sources of funding for amphibian monitoring projects in Latin America. The third appendix offers practical advice on filling out field data forms (e.g., do not use ballpoint pens!) and includes sample data sheets for transect samples, leaf litter plots, and audio samples at breeding sites. These data sheets can be easily modified to fit the specific needs of a monitoring program. The fourth appendix includes information sheets: Amphibian Mortality Information Sheet, Declining Amphibian Populations, and DAPTF Fieldwork Code of Practice.

The writing is clear and the book is well organized. Written both in English and Spanish, the manual is readily accessible for Latin American investigators. Perhaps a future version could be expanded to include Portuguese—extensive monitoring is certainly needed in Brazil. The authors do not talk down to their audience, yet the information is basic and easy to understand. I found only a couple of typographical errors, one "this data," and one sentence repeated at the end of two consecutive paragraphs. There are a few inconsistencies. For example, on p. 1 the authors state "More than a dozen amphibian species are believed to have recently gone extinct." The information sheet entitled Declining Amphibian Populations states "Now conservationists fear that at least 50 species of amphibians may already be extinct." The only area I felt could have been expanded is the section on Data Analysis. Based on my experience working with Latin Americans investigating amphibian declines, this is an area of great concern: How do we analyze and present the data? How do we compare species and sites? Perhaps in a future version of this manual the authors can expand this section to include general guidelines.

This excellent contribution will help us investigate the issue of amphibian declines by encouraging monitoring efforts. The authors intend to distribute the manual throughout Latin America. I also plan to distribute this manual to participants in my workshops and to those with whom I interact in Latin America, as the manual provides easily understandable guidelines. Much more than a tech-

niques manual, it emphasizes the what, where, and when as well as the how to monitor. The advice is practical and the techniques are inexpensive. I highly recommend that this manual be used in conjunction with Heyer et al. (1994) as the standard for field monitoring in Latin America and elsewhere.

You've done amphibians and field workers a great service, Karen, Jamie, Bruce, and Roberto. ¡Felicidades y gracias!

Herpetology, like any other discipline or scholarly endeavor, is built upon the shoulders of those who were there before us. Being scientists, herpetologists are often more interested in writing about their discoveries than about the history behind them, and they seldom write about themselves. *Life, Love, and Reptiles* is a review of the experiences and accomplishments of a man who loved herpetology, his medical career, and his wife and family. Autobiographies like this one help us understand the context within which discoveries were made and thus allow us to better understand the value of individual contributions.

Kraig Adler, in his Foreword to this book, correctly points out that professional biologists in the 19th century who worked with herps were medical doctors. John Edwards Holbrook was the notable example from that era. Most professional herpetologists in the 20th century obtained their degrees in biology, zoology, or related fields, although a few obtained their medical degree so they could also pursue herpetology. Sherman A. Minton Jr. (1919–1999) was among the latter who made important contributions to both fields.

The manuscript for this book was written by Dr. Minton in secret. His wife of 56 years, Madge Rutherford Minton, discovered it following his death on 15 June 1999. Breck Bartholomew edited the book with the help of several of Minton's long-time friends; all of whom shared memories in the side bars scattered throughout. Kraig Adler wrote the Foreword and H. Bernard Bechtel, a close friend of the Mintons and himself a medical doctor and herpetologist, wrote the Retrospective. A list of all of Minton's publications and the taxa named after him and his wife (4 modern reptiles and 1 extinct frog) conclude the book. The 6 x 9 inch hardcover book is printed in single column format. Black and white photographs are sprinkled throughout the text and collages of photos of Minton with Madge and other herpetologists appear on the inside front and back covers and end papers. There is no index. The book is well edited with few misspellings (Marines should be capitalized, pgs. 26, 28, 30; Novotny [2002] noted 3 others) or errors. It is an easy read. I highly recommend this book to herpetologists, those interested in the history of natural history, and those curious about what drives naturalists to do what they do.

Sherman (Sherm) Minton grew up in New Albany, Indiana and learned to love all things natural, especially herps, in the southern part of the state called today the Knobstone Escarpment section of the Highland Rim Natural Region (Minton 2001). He fell in love with snakes at the age of four when a rough green snake wandered near his play area while his father played golf (Stewart 2000). He always loved Indiana and wrote the first definitive herpetology of that state in 1972 (the second expanded edition was published in 2001). The first chapter in his autobiography recounts his early years, his experiences with herps in the region, going to Indiana University, meeting the love of his life Madge Rutherford, and attending medical school where he excelled in bacteriology. One inspiring teacher at Indiana who taught evolution interviewed his students, including Minton, for a far-reaching book. This was Alfred C. Kinsey, who published the first books on human sexual behavior, including *Sexual Behavior and the Human Male*. Chapter 1 ends with the start of World War II and Chapter 2 begins with that title.

Minton joined the Naval Reserve during medical school and after graduation in late 1942 began his internship at the San Diego Naval Hospital. His narratives in this chapter and the others to follow are filled with descriptions of herp trips in the region and medical and parasitological diseases. During his stint in San Diego Madge Rutherford was recruited for the Women's Army Service Pilots (WASP). She loved to fly (see Stewart, 2000) and eventually flew nearly everything the military had at the time while moving planes around the country. Minton said he worried that some glamorous flyboy would take her away from him but they stuck it out and were married in late 1943. Shortly thereafter Minton was assigned to the USS Brooks where he saw action in the Pacific theater with the Japanese, even living through a kamikaze strike on his ship. His short dependence on drugs and alcohol following these events led to his decommission from the military and return to civilian life. He took classes at the University of Michigan where he interacted with a group of renowned herpetologists and began his life-long professional study of the herps of Indiana. In 1947 he joined the Microbiology Department at the Indiana University School of Medicine, where he taught until his retirement in 1984.

Minton's memorable long-term field trips were associated with evaluations of regional medical problems. His first sabbatical was to Big Bend to study wildlife diseases and their human interac-

tions. The visits of now famous herpetologists and the herps of the region in his six month stay are chronicled in Chapter 3. His six-week stay in Costa Rica to study intestinal parasites and malnutrition is described in Chapter 4. The Mintons went to Pakistan in 1958 so that Sherman could teach microbiology to medical students in Karachi. They stayed there over four years and dealt with cholera, malaria, smallpox, a case of anthrax, and many herps. His monograph on the herps of Pakistan published by the American Museum of Natural History in 1966 was a major contribution and now a classic. Chapter 5 is the longest one in the book and includes descriptions of living in Pakistan and the numerous field trips in pursuit of herps.

The first of many field trips to Mexico (Chapter 6) was made in 1963. The Minton's oldest daughter (Brooks) was a linguist, specializing in Spanish. She eventually lived in Mexico and Sherman and Madge would make regular visits to Querétaro to visit her and her family. There isn't much herpetology in this chapter, but Minton describes the countryside and aspects of its natural history, including how to deal with "Montezuma's Revenge." The Mintons learned to SCUBA dive in the mid 1960s. Descriptions of several diving trips to Central America and the Caribbean are in Chapter 7.

In the early 1970s, Sherman Minton, by then well recognized for his research on snake venoms, was invited to participate on an expedition to study sea snakes in the south Pacific. The ship was the research vessel *Alpha Helix*, the title of Chapter 8. Minton chronicles the places visited by the crew, many of the snakes captured, their biology, and other wildlife, including birds which he liked to watch. Chapter 9 describes the itinerary of a second expedition on the *Alpha Helix* in 1975. This time he visited the site where the *USS Brooks* had been hit by the kamikaze in January 1944. A third visit to the region, this time to Australia, is also chronicled in this chapter. Minton worked on the effects of venoms from several species of snakes to determine the relationship of venom toxicity to prey type and to determine relative resistance among prey species. Madge joined him on this excursion, and Minton's portion of the book ends with them sitting on the beach at Cairns in twilight.

Chapter 10 fills in some personal attributes and history that Minton left out, likely because of his modesty. Bechtel points out that Sherman and Madge Minton worked well as a team; they co-authored two books, raised a family, and took many trips together. They loved to dance. He describes Madge's love of flying, her career in the WASPs, the feature article on her in the June 1999 issue of *Life* magazine, and her driving—"exactly the way she handled the P-47s." Madge is easily a strong role model for women. Bechtel describes Minton's life-long participation in national and international conferences and professional societies such as The Herpetologists' League and the Society for the Study of Amphibians and Reptiles. Minton received numerous awards, including the Redi Award (named after Francesco Redi who first studied snakebite in the 17th century), the highest honor bestowed by the International Society of Toxinology. He stayed active until just a few months before his death, attending the first Conference on Venomous Snake and Treatment for Snakebite in Vietnam in late 1998. Bechtel tastefully describes his cancer diagnosis and his last wishes. Stewart (2000) is another must-read account of the Minton's personal and professional histories.

I knew the kind-hearted Mintons from our brief interactions at the herp meetings. Thus, I was immensely gratified in 2001 when I drove to the meetings in Indianapolis, Indiana to see that a bridge over the Ohio River in Louisville, Kentucky (the Sherman Minton Bridge on Interstate 65) was named after a herpetologist. I learned later that Minton's father was a U.S. Senator and an Associate Justice of the Supreme Court, and of course the bridge was named for him. Still, in my mind, the bridge to Hoosier country honors the Mintons, one of whom was a herpetologist who made major contributions to the state's natural history.

Sherman Minton's autobiography shows us that he balanced many things throughout his medical career, including love of reptiles, love of his home state, love of adventure, and especially love of his wife and family. He shows us that one does not have to have a Ph.D. in biology to make long-lasting contributions. All it takes is a true love of the animals and a desire to contribute to science. Would that other herpetologists in their later years write their own autobiographies so that we can better understand and appreciate the shoulders on which we stand.

e-mail: john.moriarty@co.ramsey.mn.us

Reptiles as Pets is a Humane Society of the United States (HSUS) report detailing all that is wrong with pet reptiles and why they should not be kept. I started to read this report with great interest because of my concern and work for the conservation of wild populations of reptiles and also because of my experience as a reptile owner.

HSUS states that unregulated harvest of reptiles for the pet trade is a major problem. This may be true, but for most species habitat loss, the food trade, and harvest for skins are more serious. HSUS does not address these issues

and actually dismisses them as a smoke screen used by reptile importers.

HSUS suggests that reptiles pose a serious health risk to humans by the transmission of *Salmonella* and other pathogens. The data used by HSUS are highly suspect. They report 93,000 reptile-related salmonellosis cases annually leading to thousands of hospitalizations and 20 deaths. These numbers are from an unpublished report and are not supported by hard data. The numbers are based on an estimate that only one in 38 cases of salmonellosis is reported. The number of known cases was, therefore, multiplied by 38. The study's authors estimated 7% of salmonellosis cases are caused by reptiles, so they divided the first estimate by the second estimate. These numbers seem fuzzy to me. Based on data available to me, I suspect that there are many fewer cases of reptile-transmitted salmonellosis. In Minnesota, complete background checks are conducted on every reported case. Over the last five years the state averaged 25 reptile-related cases per annum with 3–5 hospitalizations and no deaths (J. Bender, DVM, University of Minnesota, pers. comm.). Based on the 2000 census, Minnesota has 1.7 % of the United States population. If Minnesota had an average incidence of reptile-related salmonellosis, the numbers nationally would be about 1500 cases per year, with 100 hospitalizations and few deaths. While this is still a concern, it is not the major health problem portrayed by HSUS.

The other chapters of the report deal with the health and care of reptiles within the wholesale and retail trade, including an entire chapter on the illegal trade in protected animals. Illegal activity can be found in any business. The vast majority of reptile keepers, breeders, and retailers would side with HSUS on the need to stop illegal activities. However, the presence of such activity is not a sufficient reason to ban the legal aspects of the business. I would argue that HSUS should be pushing for better enforcement of existing laws rather than condemning legitimate and illegitimate activities alike.

The report does make some good points about the numbers of animals imported, shipping techniques, and health concerns of the animals and owners. Unfortunately, rather than coming up with constructive solutions (e.g., education and training materials, better import regulations) to fix the problems, HSUS recommends the wholesale banning of the importation, collection, and keeping of reptiles. HSUS missed a great opportunity to promote the humane keeping and conservation of reptiles. The HSUS stand has caused many state herpetological organizations to distance themselves from that organization.

I cannot recommend this report because of its clear bias against the keeping of reptiles in captivity. Several organizations have responded to the HSUS report. One response that I recommend is from The Association of Reptilian and Amphibian Veterinarians (http://www.vaherper.com/nvrr/arav.htm).

PUBLICATIONS RECEIVED

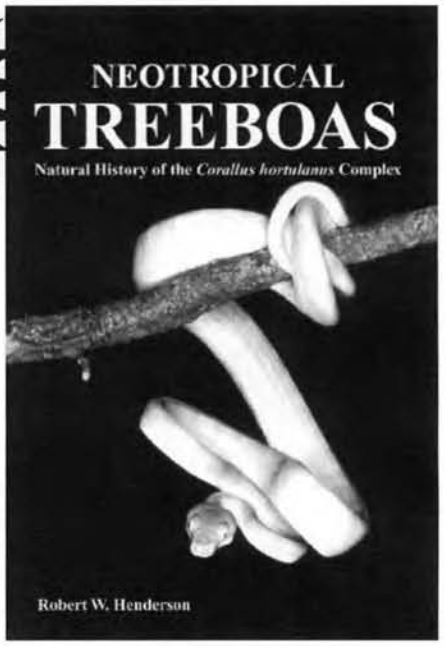
The Herpetofauna of the Mexican State of Aguascalientes, by James R. McCranie and Larry David Wilson. 2001. Courier Forschungsinstitut Senckenberg (230):1–57. [E. Schweizerbart'sche Verlagsbuchhandlung, Johannesstr. 3 A, D-70176 Stuttgart, Germany]. Softcover. Eur 16.00 (approx. US $15.00). ISBN 3-510-61073-3.

This publication presents an overview of the amphibians and reptiles of the small central Mexican state of Aguascalientes. The herpetofauna consists of 61 species (14 amphibians and 47 reptiles). Although several short field trips to the area by the authors served as the basis of the study, all literature records and the holdings of U.S. museum collections were also incorporated into the work. The monograph opens with a review of the physiography, climate and vegetation of Aguascalientes and a short ecogeographic analysis. A key to the species precedes the species accounts, which comprise the bulk of the publication. Each account includes a synonymy (including original description, first use of current combination, and all references specifically to Auguascalientes material), a statement of range, remarks (ecological, geographic, and systematic), and lists of specimens examined, literature records, and other records (each generally citing specimens by their museum numbers). Additional sections discuss species of probable occurrence (7 taxa) and species deleted from the fauna of the state. The work closes with a gazetteer of all localities mentioned and a literature cited section of approximately 300 entries. Five color plates, each with eight photos, illustrate habitats (16 photos), frogs (3), lizards (7), and snakes (14). The publication makes a significant contribution to the herpetofauna of the region and will be of interest to the many herpetologists with an interest in Mexican amphibians and reptiles.

Comparative Vertebrate Lateralization, edited by Lesley J. Rogers and Richard J. Andrew. 2002. Cambridge University Press, 40 West 20th Street, New York, NY 10011-4211, USA (www.cambridge.org). ix + 660 pp. Hardcover. US $120.00. ISBN 0-521-78161-2.

This volume provides an overview of lateralization of the vertebrate brain and its consequences for such asymmetrical functions as handedness, vocal communication, cognition and memory. Although much of the work in the field has been done on chick and primate models, the book reviews the topic in a comparative context and reptile, and especially amphibian, examples are also discussed. There are contributions from 20 researchers, presented in 15 chapters grouped into four parts: Evolution of Lateralization, Development of Lateralization, Cognition and Lateralization, and Lateralization and Memory. The evolutionary section of the book contains most of the herpetological material, much of which is based on experiments conducted with species of *Bufo* and *Anolis*. Each chapter includes an extensive bibliography and is illustrated by numerous graphs and figures derived form the primary literature in the field. The book concludes with both author and subject indices. It should be of interest to herpetologists and evolutionary

or developmental biologists with an interest in neurobiology and the mechanistic basis of behavior.



Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986–2001, *et. seq*. Privately published by and available from the author (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024, USA; e-mail: raxtell@siue.edu). Individual accounts available separately. Cost: US $0.10/page + postage and handling.

The most recent installments (numbers 24–26) in this series are *Eumeces obsoletus* (Great Plains Skink), *E. tetragrammus* (Four-lined Skink), and *Cnemidophorus uniparens* (Desert Grassland Whiptail). These new accounts comprise 21, 23, and 4 pages, respectively, in addition to detailed range maps. Axtell provides an in-depth discussion of distribution for each species in Texas, along with current taxonomy, geographic variation, conservation status, and suggestions for future work (including investigating possible hybridization between *E. tetragrammus* and *E. septentrionalis*).

Calls of New Jersey Frogs and Toads, by David M. Golden and John F. Bunnell. 2002. New Jersey Division of Fish and Wildlife, Trenton, New Jersey. CD. US $10.00. Available from: www.njfishandwildlife.com/products.htm#herpguide.

This CD contains vocalizations for the 16 species of frogs and toads native to New Jersey. Dave Golden (New Jersey Division of Fish and Wildlife, Endangered and Nongame Species Program) and John Bunnell (New Jersey Pinelands Commission) created the CD to help residents and visitors to the state accurately identify calling anurans. The majority of vocalizations were recorded by Bunnell from sites in the New Jersey Pinelands and the remaining calls were obtained from John Macgregor. The first set of tracks include vocalizations preceded by the common and scientific name of the species calling. The second group of tracks are testing tracks, to help listeners test their ability to identify the calls. Shaded distribution maps, printed on the inside of the case, indicate the occurrence of each species by county. A bar graph indicates monthly calling phenology data. This CD should prove useful to anyone interested in anuran vocalizations in New Jersey and surrounding areas.

NEOTROPICAL TREEBOAS: Natural History of the *Corallus hortulanus* Complex
by Robert W. Henderson

Treeboas (*Corallus*) occur over much of the neotropical mainland and on a number of islands. They are often conspicuous members of neotropical snake fauna, and are known for their irascible temperaments and, in some species, their highly variable color patterns. The *Corallus hortulanus* complex of treeboas comprises four species: 1) *C. cookii* on St. Vincent; 2) *C. grenadensis* on the Grenada Bank; 3) *C. hortulanus* in Amazonia, the Guianas, and Brazil's Atlantic forest; and 4) *C. ruschenbergerii* from southern Central America and northern South America. This book summarizes what is currently known about the natural history of each of the four species, with strong emphasis on *C. grenadensis*. Topics covered include color and pattern; habitat and habitat use; activity; food and foraging; predators and defensive behavior; populations; ecological relationships with other boids; and the connection between treeboas and humans. This hardcover book includes 27 graphs, 24 tables, 9 maps, and 9 black and white photos, plus 32 color photographs.

NORTH AMERICAN BOX TURTLES
A NATURAL HISTORY

By C. Kenneth Dodd, Jr.

Once a familiar backyard visitor in many parts of the United States and Mexico, the box turtle is losing the battle against extinction. In *North American Box Turtles*, C. Kenneth Dodd, Jr., has written the first book-length natural history of the twelve species and subspecies of the endangered box turtle.

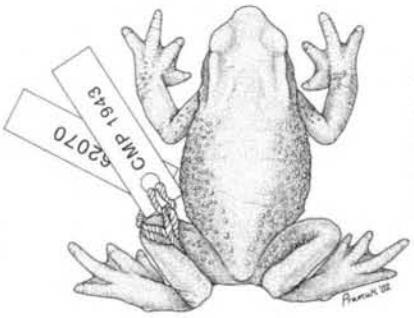
A New Herpetological Circular from the Society for the Study of Amphibians and Reptiles



Herpetological Circular 31

Herpetological Collecting and Collections Management

Revised Edition

by

John E. Simmons

Herpetological Collecting and Collections Management is the long-awaited revision of John E. Simmons' 1987 handbook. The revised edition is greatly expanded and includes all the techniques needed for field collecting and specimen management in the 21st century. Approximately 180 pp. September 2002.

"The book is excellent. I will make it required reading for all my graduate students and collection personnel."
Janalee Caldwell, Curator, Oklahoma Museum of Natural History

Artwork and Slides Wanted for *HR*

We are always interested in obtaining illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90-mm wide column. Original art, or high quality photocopies, should be packaged to ensure safe delivery and sent to the Editor. Alternatively, we would be pleased to receive material in electronic format; consult the Editor for appropriate file formats and sizes.

Also, we are interested in evaluating outstanding color slides of amphibians and reptiles for possible use on future *HR* covers. When reviewing material for submission, photographers should keep in mind the vertical format of our covers. In addition to highlighting outstanding photography, our cover subjects should lend themselves to communication of biologically interesting information through accompanying text. If you would like to have your work considered, please contact the Editor ***prior*** to sending any slides. We prefer to review images as low-resolution JPEG files before requesting examination of original slides. Postal and e-mail addresses are listed on the inside front cover.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ukans.edu/~ssar/HRinfo.html#cont>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor or Managing Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Theodora Pinou; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Ecology & Evolutionary Biology, Yale University, P.O. Box 208106, New Haven, Connecticut 06520-8106, USA. Periodical postage rates are paid at New Haven, Connecticut with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Attn. Donald Schmitt, SSAR Membership Office, P.O. Box 253, Marceline, Missouri 64658, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Breck Bartholomew, SSAR Publications Secretary (address and contact numbers on inside front cover) regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 740		US $440

A Historical Study of the Distribution of Blanchard's Cricket Frog (*Acris crepitans blanchardi*) in Southeastern Michigan

RICHARD M. LEHTINEN
University of Michigan Museum of Zoology
Division of Reptiles and Amphibians, 1109 Geddes Avenue
Ann Arbor, Michigan 48109-1079, USA
e-mail: rmlehtin@umich.edu

"We have seen it from New Jersey to Georgia, Louisiana, Texas and Iowa, but like most workers we have neglected this most ubiquitous tree frog. Everyone remarks their choruses." (Wright and Wright 1949)

Unfortunately, Wright and Wright's (1949) characterization of the abundance of *Acris crepitans* is no longer accurate. In recent years, there have been numerous reports of declines in populations of Blanchard's cricket frog (*Acris crepitans blanchardi*), particularly in the midwestern US and adjacent Canada (e.g., Minnesota [Oldfield and Moriarty 1994]; Wisconsin [Hay 1998; Mossman et al. 1998]; Iowa [Hemesath 1998; Lannoo et al. 1994]; northern Illinois [Mierzwa 1998]; northern Indiana [Brodman and Killmurry 1998]; Ontario [Oldham 1992]). Frost (1983) and Hammerson and Livo (1999) have also reported declines from the western edge of its range.

In Michigan, Blanchard's cricket frog was historically widely distributed in the southern half of the lower peninsula (Harding 1997; Ruthven et al. 1912). Isolated records also exist for populations in the northern portion on the lower peninsula (Lee 1998; Ruthven et al. 1912). However, there has been no recent, published report of the current distribution of these frogs in Michigan. Surveys by the Michigan Department of Natural Resources and data from the Michigan Frog and Toad Survey indicate that this species is still somewhat abundant in southwestern Michigan, but is rare in the southeastern part of the state (Lee 1998).

Long-term monitoring of distribution and abundance is critical to the ability to detect and respond to declines (Pechmann and Wilbur 1994). Museum specimens, when accompanied with appropriate locality data, provide unequivocal evidence of the occurrence of a species at a certain time and place. These, and other records, provide us with information on the historic distribution of a species and can be used in conjunction with contemporary surveys to assess its current distribution and conservation status (Shaffer et al. 1998).

To assess the historic distribution of Blanchard's cricket frog in southeastern Michigan, I compiled a database of historic localities for this species in 14 counties in southeastern Michigan, USA. This database was based on records from museums, the scientific literature, the Michigan Natural Features Inventory, the Michigan Frog and Toad Survey, and reports from local naturalists. I limited my search for historical information to the following counties in southeastern Michigan: Genesee, Hillsdale, Ingham, Jackson, Lapeer, Lenawee, Livingston, Macomb, Monroe, Oakland, Shiawassee, St. Clair, Washtenaw and Wayne. A total of 79 historic localities were found in the study area dating from 1878 to 1999. These historic localities included three habitat types: lakes (35%), ponds (39%) and rivers or streams (26%).

A difficulty in conducting historical studies is that the quality of information varies greatly, particularly in older records. For example, many specimens or literature records simply refer to a township or a city, (e.g., "Norvell Township" or "Ann Arbor") without any specific locality data. Also, some older records use long forgotten names (e.g., "Steere's marsh" or "Fiegel's woods"). Some of these were located after consulting old maps, but others had to be excluded from further consideration. In all, 60 localities were sufficiently informative that they could be relocated and surveyed.

Chorusing surveys were conducted at these 60 sites for Blanchard's cricket frogs during the peak breeding season. At each site, after a five minute acclimation period, I listened ten minutes for vocalizations of male cricket frogs. If cricket frogs were detected, I attempted to collect a reference specimen. Chorusing surveys were conducted between 2000 and 0100 h. The minimum air temperature to conduct a chorusing survey for cricket frogs was

FIG. 1. Location of sixty historical localities (1878–1999) for *Acris crepitans blanchardi* in fourteen counties in southeastern Michigan, USA. Open circles represent extinct populations, shaded circles represent extant populations, based on 2001 surveys.

18°C. Chorusing surveys were not conducted if it was raining heavily. Surveys began on 18 May and ended on 9 July, 2001. Each site was visited once.

Only two of the 60 sites surveyed (3%), had extant populations of cricket frogs (Fig. 1). One is located in Lenawee County in an abandoned gravel pit on a nature preserve. Previous work at this site indicates that other ponds in the preserve also have cricket frogs (R. Lehtinen, unpubl. data). The other site is a pond in a rapidly urbanizing area of Ypsilanti in Washtenaw County. Construction has already begun on a housing development on the east side of this site. Both of these sites had relatively large numbers of cricket frogs and full choruses of males and successful reproduction were detected. A reference specimen from the Lenawee County site was deposited at the Division of Reptiles and Amphibians at the University of Michigan Museum of Zoology (UMMZ 227792).

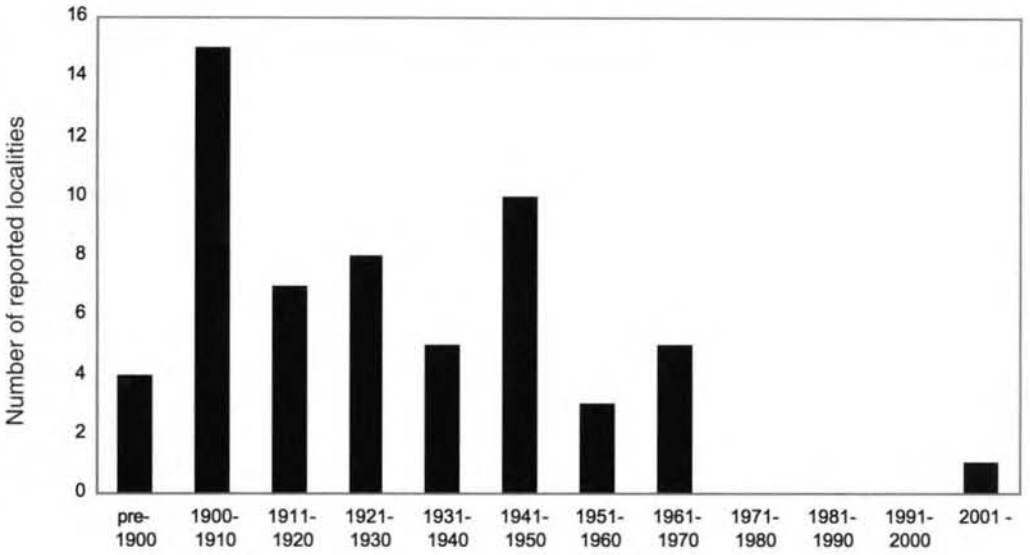

FIG. 2. Number of sites in southeastern Michigan, USA where *Acris crepitans blanchardi* specimens were collected, 1878–2001.

To estimate the timing of the decline, I tabulated the number of sites in southeastern Michigan from which cricket frogs had been collected in ten year intervals from pre-1900 to the present using all available museum specimen data (FIG. 2). While sampling effort was not uniform over this time period, this data does give a qualitative estimate of the timing of the decline. Reasonably large numbers of extant sites are present in each decade until the 1970s. As populations well into northern Ohio and Indiana (Lipps 2000; R. Brodman, pers. comm.) also seem to be declining, it seems likely that this decline began at least thirty years ago.

The decline in Blanchard's cricket frogs in southeastern Michigan is not novel, as every other state in the upper Midwest has reported similar trends (Minnesota [Oldfield and Moriarty 1994]; Wisconsin [Hay 1998; Jung 1993]; Iowa [Hemesath 1998; Lannoo et al. 1994]; Illinois [Mierzwa 1998]). In 1996–1997, Lee (1998) found six extant populations in southeastern Michigan, although some of these were based on volunteer data and might have been erroneous (see discussion below). Cricket frog populations in southwestern Michigan seem to be doing better than in the southeastern part of the state, with at least 41 sites known according to Lee (1998).

States adjacent to Michigan have also reported declines. In northwestern Ohio, Lipps (2000) conducted surveys for cricket frogs in fifteen counties from 1997 to 1999. He found extant populations at 18 out of 99 historical sites (18%, nine out of fifteen counties) and concluded that *Acris* is much less abundant in northern Ohio than in the past. Similarly, Brodman and Kilmurry (1998) found that cricket frogs had been extirpated from Jasper County in northwestern Indiana and have declined throughout much of the northern part of the state (R. Brodman, pers. comm.).

Only two of eleven sites in southeastern Michigan reported to have cricket frogs by Michigan Frog and Toad Survey volunteers (1996–1999) were found to be extant. There are three likely (and non-mutually exclusive) explanations for this discrepancy. Firstly, these populations might have very recently gone extinct. Secondly, due to sampling error, I might have failed to detect cricket frogs in my surveys at these sites. This is relatively unlikely as cricket frog vocalizations are conspicuous and surveys were carried out during the most favorable periods. Or thirdly, cricket frogs might have been erroneously reported from these areas. This is particularly likely for sites that were never confirmed by an expert.

Many causal factors have been suggested to explain the decline of Blanchard's cricket frog. These include introduced predators or competitors (Lannoo et al.1994), agricultural chemicals (Jung 1993; Oldham 1992), wetland alteration (Lannoo 1998), prolonged droughts (Lannoo 1998), acid deposition (A. Resetar, unpubl. data), and habitat change (Hay 1998). The most commonly cited reason for amphibian declines is habitat loss and degradation (Pechmann and Wilbur 1994). In this study, three sites (5%) had been destroyed since the original data was collected. Eleven other sites (18%), while still in existence, have been modified to such an extent that, in my estimation, they no longer represent useable habitat. This was most often noted at lakes where the shorelines had been completely developed. Clearly, habitat loss and degradation has been an important factor in some cases for cricket frogs in southeastern Michigan. While there is little data currently available to test rigorously any of these hypotheses, the natural history of the species might give us important clues into the causes of this decline.

Firstly, cricket frogs are early successional species (Harding 1997). On the E.S. George Reserve in Livingston County, Michigan (an area where cricket frogs once occurred—see Collins and Wilbur 1979), Skelly et al. (1999) reported that forest cover had increased from 30% in 1937 to 67% in 1999 (see also Roller 1974). In addition, Hart (1968) reported that more than 1.6 million ha of farmland were abandoned in Michigan between 1910 and 1959, most of which reverted to forest. These successional trends are typical of eastern North America (Goigel Turner and Ruscher 1990) and can have a great influence on the distribution of amphibians (Werner and Glennemeier 1999).

Secondly, cricket frogs are short-lived. Data from Kansas, Louisiana, and Texas indicate that the average life expectancy of a cricket frog is about four months, only 5% of the population survives the winter, and complete population turnover takes place every 16 months (Bayless 1966, 1969; Burkett 1984). These demographic facts, combined with a modest dispersal capacity (see Pyburn 1958), greatly predispose this species to periodic local extinction.

Lannoo (1998) has suggested that metapopulation structure interacting with environmental stochasticity (i.e., droughts) and anthropogenic changes in habitat quality might have resulted in the observed declines. In the past, when wetland habitats were more abundant and less isolated, populations might have been more buffered from extinction by immigration (the "rescue effect"—Brown and Kodric-Brown 1977) and areas experiencing local extinction might have been recolonized relatively easily. In the current landscape, isolation and dispersal barriers might result in higher extinction rates and lower recolonization rates.

Metapopulation theory suggests that when the number of suitable patches in a metapopulation is reduced, extinction of the entire metapopulation becomes increasingly probable (the "extinction debt"—Tilman et al. 1994). Therefore, over time, the loss of individual populations will reduce the viability of the entire metapopulation. The threshold number of suitable patches needed for metapopulation persistence has been termed the minimum viable metapopulation size (Hanski et al. 1996). This approach could be used to predict the vulnerability and dynamics of cricket frog metapopulations in different landscapes. Unfortunately, no empirical information is currently available on cricket frog metapopulation dynamics.

Local extinctions are a frequent occurrence in metapopulation dynamics (Marsh and Trenham 2001). Therefore, we would expect a certain proportion of historic sites to be unoccupied, even in the absence of any decline. Then, the question is, how many local extinctions indicate a decline? In this case, 58 of 60 historic populations (97%) appear to be extinct, with no other populations known in the area. I conclude that Blanchard's cricket frogs are not only declining, but are nearly extirpated from southeastern Michigan.

Metapopulation structure, habitat loss and alteration, and regional successional trends might be important factors in the decline of Blanchard's cricket frog. If these factors are the primary causes of declines in this species, habitat restoration (including wetland and grassland/oak savanna restoration) combined with repatriation of cricket frogs to suitable areas should be effective conservation measures. Alternately, if other mechanisms are primarily responsible for cricket frog declines (e.g., introduced predators or competitors), repatriated cricket frog populations will not persist.

What is required now, rather than further speculation, are empirical tests of these (and other) causal mechanisms. Comparative data on population dynamics would be particularly useful in areas where cricket frogs are declining and where they are not declining.

Acknowledgments.—I thank M. Lehtinen for help in the field and C. Clampitt, Y. Lee, G. Lipps, D. Blanchard, R. Bailey, R. Nussbaum, A. Kluge, L. Sargent, and D. Szczygiel for data and information. Comments from J. Harding and M. Lannoo improved this manuscript. I also owe a debt of gratitude to the many herpetologists who collected the data on which this study was based. I also thank the Michigan chapter of The Nature Conservancy for access to their property. The Michigan Department of Natural Resources Nongame Wildlife Fund funded this project. All specimens and data were collected under Michigan Scientific Collectors Permit CO942, Threatened / Endangered Species Permit 00-1145, and DNR Parks and Recreation Division permit BO-13-2001.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 33, Number 1 (March 2002). However, please take note of the updated information below.

Current section editors: **Marc P. Hayes** (amphisbaenids, crocodilians, lizards, and *Sphenodon*; mhayesrana@aol.com); **Charles W. Painter** (amphibians; cpainter@state.nm.us); **Gordon W. Schuett** (snakes; gschuett@asu.edu); and **James Harding** (turtles; hardingj@pilot.msu.edu). Electronic submission of manuscripts is required (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments). Authors without the ability to send manuscripts electronically may supply hard copy instead. Figures can be submitted electronically as JPG files, although higher resolution TIFF or BMP files will be requested for publication. If figures cannot be provided in this format, you may send them to the section editor for scanning. Additional information concerning preparation and submission of graphics files is available on the SSAR web site at: http://www.ukans.edu/~ssar/HRinfo.html.

CAUDATA

AMBYSTOMA LERMAENSE (Lake Lerma Salamander). **REPRODUCTION and DEVELOPMENT**. *Ambystoma lermaense* is an endemic and endangered species from the Estado de México, México. Here we provide the first data on reproduction and development of this species. On 3 July 1995 we collected four *Ambystoma lermaense* (two males and two females) at San Pedro Tlaltizapán Lake (19°12'34"N, 99°30'26"W) Municipio de Tianguistenco, Estado de México, México. The specimens were transported to the laboratory at Facultad de Ciencias, Universidad Autónoma del Estado de México in an 18.9-liter water container. During transportation, one female (TL 192 mm; SVL 101 mm; mass 35.1 g) began to lay eggs at 1215 h and continued until after we reached the laboratory at about 1325 h. Adults and eggs were separated and placed in aquaria with continuous aeration of water from the collecting locality; pH was 8.2–8.5.

Clutch size was 841 eggs. In a sample of 40 eggs, the average ovum diameter was 2.40 ± 0.36 mm (range 1.8–3.9) and the external capsule diameter was 7.59 ± 0.64 mm (range 6.0–8.7). Egg fertility was low (26%). Embryonic development to hatching took 240–250 hours at 16.5–21.0°C. Embryo mortality was 10%. A total of 196 embryos hatched at stage 39 or 40, and hatchling size was 9–10 mm. After several months in captivity, the female died and was deposited in the Colección Nacional de Anfibios y Reptiles, Instituto de Biología, Universidad Nacional Autónoma de México (IBH 11400). These observations were part of a project supported by CONACYT of México (Proyecto1165P-N) and Universidad Autónoma del Estado de México (Clave 995/94).

Submitted by **XÓCHITL AGUILAR-MIGUEL**, Centro de Investigación en Recursos Bióticos, Facultad de Ciencias, Universidad Autónoma del Estado de México, Instituto Literario #100, Toluca, Edo. de México, México, C.P. 50000 (e-mail: xam@coatepec.uaemex.mx), **GUSTAVO CASAS-ANDREU**, Instituto de Biología, Universidad Nacional Autónoma de México, A.P. 70-153, 04510, México, D.F., México (e-mail: gcasas@servidor.unam.mx), and **EDUARDO PINEDA-ARREDONDO**, Instituto de Ecología, Xalapa, Veracruz, México.

ANURA

ADENOMERA aff. ***MARMORATA*** (NCN). **REPRODUCTION**. The first reports on reproduction in the genus *Adenomera* dealt with populations in southeastern Brazil, and indicated a highly terrestrial reproductive mode (Lutz 1931. C. R. Soc. Biol. Paris 109:755–756; Lutz 1947. Copeia 1947:242–252). Subsequent inferences derived from larval morphology supported this notion for a species in the Amazon Basin (Heyer and Silverstone 1969. Field. Zool. 51[11]:141–145), and the idea became generalized for the group. However, there was some indication from preserved larvae that perhaps reproduction was not as terrestrial in certain populations in southeastern Brazil (Heyer 1973. Contr. Sci. Nat. Hist. Mus. Los Angeles Co. 251:1–50), but this was not conclusive (De la Riva 1996. J. Herpetol. 30:556–558). Herein we report on the reproductive mode of a population in southeastern Brazil. On 30 September 2000, three *Adenomera* foam nests were found and collected beneath leaf litter, each in a small chamber in the ground. The general habitat is a cocoa plantation within an alluvial forest in the locality of Povoação (19°33'S, 39°46'W), 30 km from the town of Linhares, Espirito Santo, Brazil. The foam nests were roughly elliptical in shape and had a maximum diameter of 4 cm; ca. 3 cm were below ground level. One of the nests contained cream-colored eggs with an average diameter of 3 mm (N = 3), from which 29 tadpoles emerged; the other two nests already had 27 and 28 brown tadpoles. The foam had dried up 9 days later, and

in one of these nests the tadpoles had perished; in the other two they were still alive, and water was added. The following day the foam had been reconstituted. A few days later (23 October 2000) the earthen chambers crumbled apart and 28 tadpoles were placed in water. Before this they seemed to stall development at stages 25–27 (*sensu* Gosner 1960. Herpetologica 16:183–190) for 23 days. In the next few days these tadpoles increased dramatically in size, developed a sinistral spiracle, and were feeding on fish food and lettuce. The first metamorph emerged 77 days after the collection date. Our observations support the notion that this population exhibits a more aquatic reproductive mode than that previously described for the group in southeastern Brazil, and more similar to that reported by De la Riva (1995. Stud. Neotrop. Fauna Environ. 30:15–29).

The genus is currently undergoing significant taxonomic changes. We have termed this population as *Adenomera* aff. *marmorata* as we know it is not the same species as that reported by Kwet (1998. Herpetol. Rev. 29:48) because of distinct advertisement calls. Specimens will be deposited at the Museu de Biologia Mello Leitão – MBML, Santa Teresa, Espírito Santo.

We thank W. R. Heyer for reviewing this manuscript. Support for AA was provided by operating NSERC grant #4946 to G. K. Morris. Thanks to R. Penha da Silva for field work assistance.

São Mateus, 1458 - Bairro Araçá, Linhares, Espirito Santo, Brazil, CEP 29.901-350; *Current address of AA: Department of Zoology, Erindale College, University of Toronto, Mississauga, Ontario, L5L 1C6, Canada; e-mail (APA): tonim@escelsa.com.br; (AA): ariadne@zoo.utoronto.ca.

ELACHISTOCLEIS OVALIS (NCN). **DEFENSIVE BEHAVIOR**. Defensive behavior is quite variable in anurans, particularly among Leptodactylidae, Hylidae, and Bufonidae (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins Univ. Press 670 pp.). On 6 September 2000, we collected an adult male *Elachistocleis ovalis* (Museu de Biodiversidade do Cerrado [AAG-UFU] 2118) (SVL 20.3 mm) in Nova Aliança municipality (21°11'S, 49°42'W), São Paulo State, Brazil. While being manipulated for photographs during the daylight, the specimen assumed a defensive behavior: pushing the forelimbs against the ground, stretching the hind limbs out perpendicular to the body, raising the ventral region off the soil surface, and inflating the lungs. This stationary posture was held for 20 sec. A similar posture has been observed in *Xenohyla truncata* (Napoli 2001. Herpetol. Rev. 32:36–37), *Hyla geographica* (Azevedo-Ramos 1995. Rev. Brasil. Biol. 55:45–47), and *Scythrophrys sawayae* (Garcia 1999. Herpetol. Rev. 30:224). Orange stripes evident on the posterior region of the hind limbs might function as aposematic coloration.

We thank Ariovaldo A. Giaretta for critically reading this manuscript; fellowship by CNPq to MNCK and CAPES to MM.

PHYSALAEMUS PUSTULOSUS (Tungara Frog). **DISPLACEMENT OF AMPLECTANT MALES.** Aggressive behavior is common during the sexual behavior of many anurans. Aggressive behavior during courtship has been occasionally observed in *Physalaemus pustulosus* (Ryan 1985. The Tungara Frog. The University of Chicago Press. 230 pp). Males were occasionally observed trying to pull off amplectant males; however, these attempts were all unsuccessful. Ryan also reported that males of *P. pustulosus* emit a "release call" when they are clasped by another male.

Here we describe the aggressive behavior of a male *P. pustulosus* that successfully displaced a larger amplectant male. On 6 October 2000 (2214 h), we observed a male *P. pustulosus* (SVL 30 mm) trying to remove an amplectant male (SVL 33 mm) from the back of a female (SVL 34 mm) in Golfito, Puntarenas Province, SE Costa Rica (8°40'N, 83°10'W). The intruder bit the thigh and foot of the amplectant male several times, pulling him forcefully while emitting a release-like call. The amplectant male kicked the aggressor several times and the couple moved away several centimeters. The intruder followed the couple and again began the release-like call, and then tried to separate the pair by pushing his head between their bodies. Then he bit the amplectant male on the waist and emitted a release-like call. The amplectant male kicked the intruder, pushing him aside, but the aggressor returned quickly and seized the amplectant male by the armpits. Approximately 26 minutes after we first saw them, the intruder pulled the amplectant male off of the female and immediately mounted her and seized her by the armpits. The displaced male tried unsuccessfully to recover the female, but the couple swam away from the displaced male.

Contrary to the observations of Ryan (1985, *op. cit.*), this male was able to remove an amplectant male. Interestingly the winning male was of smaller size. We suggest that the release-like call emitted by the intruder male could be a sensory trap (Ryan 1999. Science 283:1083a) to facilitate removal of the amplectant male.

We thank Gilbert Barrantes, Robert Puschendorf, and William Eberhard for their valuable comments and revisions of this note. These observations were carried out on a field trip of the amphibian course of the Escuela de Biología, Universidad de Costa Rica.

TESTUDINES

CHELODINA EXPANSA (Broad Shell River Turtle) and ***EMYDURA SIGNATA*** (Brisbane Shortneck Turtle). **REPRODUCTION**. In several species of freshwater turtle, the administration of oxytocin for egg collection (Ewert and Legler 1978. Herpetologica 38:314–318) has triggered nesting behavior in gravid females. For example, this occurs in the snapping turtle (*Chelydra serpentina*), wood turtle (*Clemmys insculpta*), and musk turtle (*Sternotherus carinatus*) (Ewert 1979. *In* M. Harless and H. Morlock [eds.], Turtles: Perspectives and Research, pp. 313–413. John Wiley and Sons Inc., Florida.). Tucker et al. (1995. Herpetol. Rev. 26:138) reported that administration of oxytocin could also induce nesting behavior in female red-eared sliders (*Trachemys*

scripta elegans) hours after they deposited eggs. This nesting behavior was attributed to the continued hormonal effects of oxytocin in turtles following induction. If the administration of oxytocin triggers nesting behavior as is suggested by the above observations, then nesting behavior is less likely to occur many days after oxytocin administration as its concentration in the body will have returned to pre-injection levels (Plumb 1999. Veterinary Drug Handbook 3rd Edition. Iowa State Univ. Press, Iowa. 750 pp.). Here I report nesting behaviors in two species of Australian freshwater turtles (*Chelodina expansa* and *Emydura signata*) many days after collection of their eggs through administration of oxytocin.

A female *C. expansa* was captured leaving the water after heavy rain to nest at the University of Queensland lakes, St Lucia, Australia on 6 May 1999. X-ray revealed 14 oviducal eggs. Initial administration of oxytocin (Syntocin, 1.5 ml/kg) yielded only two eggs over two days. A second x-ray revealed that no eggs had been broken and were preventing further oviposition. Calcium gluconate (Theracalcium, 1.0 ml/kg) was administered (McArthur 1996. Veterinary Management of Tortoises and Turtles. Blackwell Science Ltd., Oxford. 176 pp.) the night prior to a second administration of oxytocin at 1100 h the following morning. Eleven eggs were deposited within 1.5 h. The final egg was laid later that day.

This female was kept in captivity for a period of 10 days after egg harvesting and was marked by scute notching prior to release. Five days later (i.e., 15 days following the second dose of oxytocin and the deposition of all eggs) the same female (identification by scute notching) was found carrying out nesting behavior during heavy rain. She was observed to complete nesting behavior including backfilling of the nest and compacting the nest plug. Excavation of the nest indicated a proper egg chamber of typical size for a *C. expansa*; however, the nest contained no eggs.

This behavior has also been observed in *E. signata* from the same site on 27 October 1999. Several females were captured and x-rayed to reveal egg numbers. Two of the females who were induced to lay their eggs via oxytocin injection, were found attempting to nest many days after oviposition. The first female laid 21 of 21 eggs in the lab and was found attempting to nest 21 days after oviposition. A second female who laid 18 out of 18 eggs upon oxytocin induction was found attempting to nest 21 days after oviposition. All of these females left the water to attempt nesting during heavy rain, which suggests that rain may be an important nesting cue.

Clearly these findings demonstrate that oxytocin administration per se was not the cause of the nesting behavior observed in these cases. Oxytocin caused the uterine contractions directly associated with egg laying, however it is clear that other factors are the cue for nesting behavior and that there are probably many behavioral and hormonal steps involved in completing a nesting bout. If a female on her way to nest is captured and her eggs gathered artificially by oxytocin administration, an important instinctual behavior associated with oviposition, i.e., nest construction is not completed and it appears that the female perceives she is still carrying eggs. This perception may be attributed to the failure of a normal nesting-related hormonal sequence to occur during artificially induced oviposition.

For example, Guillette et.al. 1991 (Gen. Comp. Endocrinol. 82:121–130) found that in loggerhead turtles (*Caretta caretta*) a hormonal sequence takes place from the onset of body pitting (or the start of the nesting process). They found that the onset of body pitting induced the release of Arginine Vasotocin (AVT), which in turn induced the synthesis and release of Prostoglandin F (PGF). Prostoglandin E_2 (PGE_2) is released at the same time as PGF however the stimulus for the synthesis and release of this hormone is unknown. All three hormones (AVT, PGF, PGE_2) then act to promote uterine contractions and therefore egg laying. Therefore, behavior associated with nest site choice and beginning to dig a suitable nest may be important to the endocrinology of oviposition in that it might initiate the hormonal sequence necessary to complete the laying bout. If this type of hormonal sequencing occurs in all turtles, females in which oviposition is artificially induced might still perceive they are gravid until they have had the chance to go through a complete nesting procedure and thus undergo the successive hormonal sequence associated with nest construction.

The discovery of non-gravid *C. expansa* and *E. signata* females attempting to nest many days after oxytocin injection and egg harvesting, suggests that these species might exhibit a sequence of hormone release similar to that of *Caretta caretta* where behaviors associated with nesting (e.g., body pitting or beginning to dig the nest) trigger the beginning of the hormone sequence and the nesting bout (Guillette et al., *op. cit.*). Endocrine studies on the different stages of hormone release in these species would need to be undertaken however, before this can be confirmed.

CHELONIA MYDAS (Green Sea Turtle). **ADULT MALE SIZE.** Only a handful of studies have reported on adult male sea turtles (Booth and Peters 1972. Anim. Behav. 20:808–812; Limpus 1993. Wildl. Res. 20:513–523; Limpus 1994. Mem. Queensland Mus. 35:139–154). A major logistical difficulty is finding and observing adults in the marine environment. Serendipitously, we have been able to observe and capture adult male *Chelonia mydas* in Atol das Rocas, Brazil (3°52'S, 33°49'W) while they are available in the central lagoon of this ring-shaped atoll at high tide. On several separate occasions, from 1990 through 1997, males were captured by hand during free dives. While still in the water, they were tagged with monel or inconel tags, and were measured for curved carapace length and width (CCL and CCW). A total of 48 *Chelonia mydas* males were captured a total of 56 times. The males were on average smaller than nesting females from Atol das Rocas (t = 12.5, $p < 0.0001$, Welch t-test,, see Table 1), which is not unlike the green turtle populations in Australia (Limpus 1993, 1994, *op cit.*).

Few females were captured in the central lagoon, despite the fact that many females nest in Atol das Rocas during the nesting season (Bellini and Sanches 1996. Marine Turtle Newsl. 72:1–2). It is likely that most females remain in the waters outside the ring-shaped atoll, although dangerous diving conditions kept us from investigating these areas in detail. On a few occasions, we came across pairs of copulating turtles, usually accompanied by several extra males, but no captures were made. On three separate occasions, copulating pairs of *Chelonia mydas* were observed up on the beach; on one of these occasions in 1991, the female successfully nested with a male (100.0 cm CCL) securely attached to her carapace.

TABLE 1. Carapace size (mean ± SEM) of *Chelonia mydas* males in the waters of Atol das Rocas, Brazil. Data for nesting females are from Bellini and Sanches (1998. Anais Semana Nacional de Oceanografia, 11, Rio Grande, RS, pp. 335–337).

	Males	Nesting Females
CCL (cm)	105.4 ± 0.84	115.9 ± 0.001
N	45	1702
range	85.0–118.0	100.0–134.0
CCW (cm)	97.1 ± 1.15	107.6 ± 0.001
N	43	1147
range	69.0–110.0	94.0–123.0

We are grateful to Augusto C. C. D. da Silva and Jaqueline C. de Castilhos and everyone else who helped with the captures. Thanks to N. Mrosovsky for stimulating us to publish these data, to M. H. Godfrey for helping with the translation, and to the Reserva Biologica do Atol das Rocas - IBAMA for logistical support. Projeto TAMAR-IBAMA is co-managed by the Fundação Pró-TAMAR and is officially sponsored by Petrobras.

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **SIZE.** Carapace length and mass are nearly exclusively used as indicators of body size in sea turtles. Of the two, carapace length is more often measured, because of the logistic challenges associated with weighing animals that might exceed several hundred kilograms. Carapace length can be converted to body mass using previously published formulae (e.g., Boulon et al. 1996. Chel. Conserv. Biol. 2:141–147; Leslie et al. 1996. Chel. Conserv. Biol. 2:159–168). The carapace of *D. coriacea* lacks the thickened bony plates typically associated with hard-shelled turtles, and is composed of a mosaic of small irregular ossicles that can be less than 5 mm thick. The carapace of *D. coriacea* terminates at the caudal end in a thin peduncle (Fig. 1a), which comprises one end of the midline used in standard carapace measurement as described by Bolten (1999. *In* Eckert et al. [eds.], Research and Management Techniques for the Conservation of Sea Turtles, pp. 110–114. IUCN/SSC Marine Turtle Specialist Group Publication No. 4). This unique anatomy increases susceptiblity to abrasion and damage; indeed, up to 20% of nesting *D. coriacea* might have visible wounds, either fresh or healed, on the carapace, with many having damaged or missing (Fig. 1A) peduncles (Fretey 1981. Rev. fr. Aquariol. 8:199–128; Rueda-A. et al. 1992. *In* Rodriguez-Mahecha and Sanchez-Paez [eds.], Contribucion al Conocimiento de las Tortugas Marinas de Colombia, Libro 4, pp. 1–131. Serie de Publicaciones Especiales del INDERENA, Santafe de Bogota, Colombia). These injuries can be caused by predators such as sharks, killer whales, or billfish (Eckert et al. 1994. Herpetol. Rev. 25:63–64; Frazier et al. 1994. Envir. Biol. Fishes 39:85–96), and from debris on nesting beaches (Fretey, *op. cit.*; B. Godley, pers. comm.). These injuries complicate accurate measurement and lead to inconsistency in data collection.

As a potential solution to this problem, we investigated the correlation between curved carapace length (CCL) and length of the second pair of keels parallel to the midline keel of the carapace in *D. coriacea* with undamaged peduncles, to see if this measurement would have utility as an estimator of CCL in individuals with peduncle damage. We measured the carapaces of nesting female *D. coriacea* on Awala-Yalimapo Beach in French Guiana, from 23 May–2 June 2000 and 14–21 July 2001. We limited the measurements to a span of 10 days or less to avoid remeasuring the same female, as the within-season renesting interval for *D. coriacea* in French Guiana is about 10 days (Girondot and Fretey 1996. Chel. Conserv. Biol. 2:204–208). For nesting females without any carapace deformities, CCL was measured as described in Bolten (*op. cit.*): using a flexible metal measuring tape laid on the lateral side of the midline keel from the nuchal notch to the end of the caudal peduncle (Fig. 2). Side keel length was measured on both sides of the midline, from the anterior edge of the carapace to the posterior edge, alongside the keel ridge (Fig. 2). We chose the second parallel keel, rather than the first, because the latter terminates towards the end of the caudal peduncle, and thus injuries that affect midline CCL measurement would also likely affect the measurement of the first parallel keel. In all cases, the tape was laid flat, to the right of and as close as possible to the midline of the keel. Measurements were recorded to the nearest 0.5 cm. Simple correlation coefficients were determined and significance analyzed by an *F*-test (Zar 1999. Biostatistical Analysis. Prentice Hall, Upper Saddle River, New Jersey. 663 pp).

Mean ± SD CCL from 91 adult female *D. coriacea* was 158.2 ± 7.7 cm (range = 139–180 cm), while left side keel length (SKL) was 113.5 ± 6.2 cm and right SKL was 113.3 ± 6.1 cm (absolute mean length difference between left and right SKL = 1.6 ± 1.9 cm, range = 0–13 cm). The correlation coefficient (r) between CCL and left SKL was 0.80 (Fig. 3). The correlation coefficient (r) between CCL and right SKL was also 0.80, and both of these correlation coefficients were significantly different from zero ($p < 0.0001$). The correlation between left and right keels was also highly significant ($r = 0.92$, $p < 0.0001$), as was the correlation between CCL and the mean value of the two side keels ($r = 0.82$,

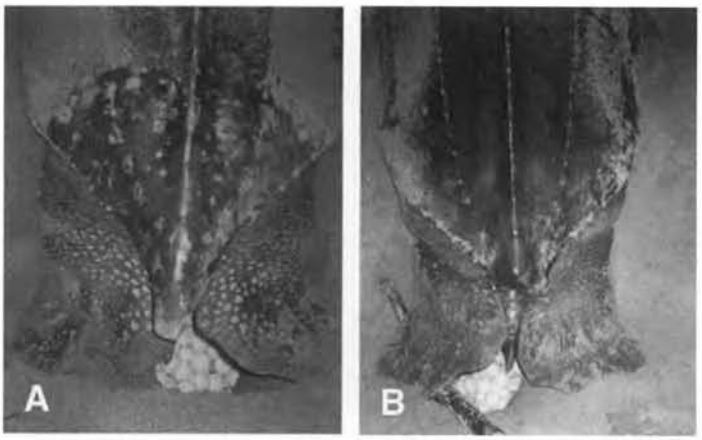

FIG. 1. A) Posterior half of carapace of a nesting *D. coriacea*, with an intact terminating peduncle. B) Posterior end of carapace of a nesting *D. coriacea* turtle with damaged terminating peduncle.

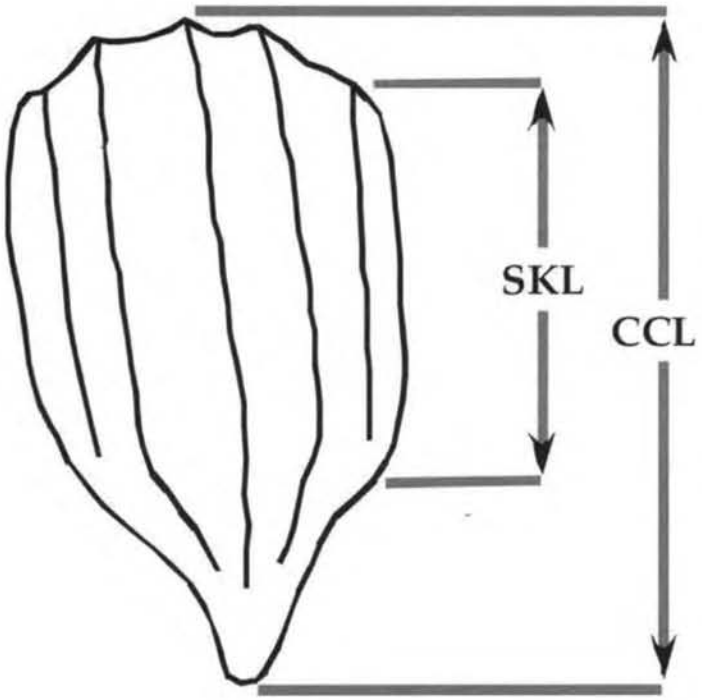

FIG. 2. Schematic representation of measurements collected from nesting *D. coriacea* females in French Guiana.

$p < 0.0001$). The equation for the linear relationship between left SKL and CCL is $Y = 0.995X + 45.26$, where X is the left SKL and Y is CCL. The equation for the right side keel is $Y = 1.008X + 44.06$. These equations can be used to estimate CCL from SKL for *D. coriacea* with damaged carapaces.

Based on our observations, it is possible to use SKL to estimate CCL. We found a significant correlation between SKL and CCL in non-injured *D. coriacea*. However, the correlation was not strong. It might be the case that the relationship between these two measures changes according to body size, perhaps with a different relationship for juveniles or subadults, and a likely difference between males and females. We also suspect that the relationship between these two measures might be population specific; hence we recommend that prior to using SKL as an index of CCL in other populations, a similar correlation analysis be performed. The variation in the relationship between side and center keel length in *D. coriacea* is also likely to be affected by the degree of curvature of the carapace. On high density nesting beaches in French Guiana and Suriname, we have observed a wide range of variation in curvature of the carapace of *D. coriacea*, ranging from oblique to sharp, and occasionally we have seen kyphotic individuals. This variation in curvature is not limited to *D. coriacea*, but is seen in other species of turtles, and is likely because of developmental defects (Tucker 1997. Bull. Maryland Herpetol. Soc. 33:171–177). One way to minimize the influence in variation in curvature is to collect straight-line measurements (Bjorndal and Bolten 1989. Bull. Mar. Sci. 45:189–192; Frazier, *op. cit.*). However, the calipers required to take straight-line measures are large and awkward, reducing their practicality in difficult and isolated field conditions. In many situations, including ours, CCL is the only feasible option for measurement of *D. coriacea*. In some cases, the carapace damage of nesting females affects an area large enough to impede measurement of the side keel length. If both sides of the carapace are damaged, we recommend excluding data from that individual from a dataset on standard lengths. However, we suggest that this method of estimating CCL will enable researchers to include more individuals in their studies, and will help standardize the measurement of CCL in *D. coriacea*.

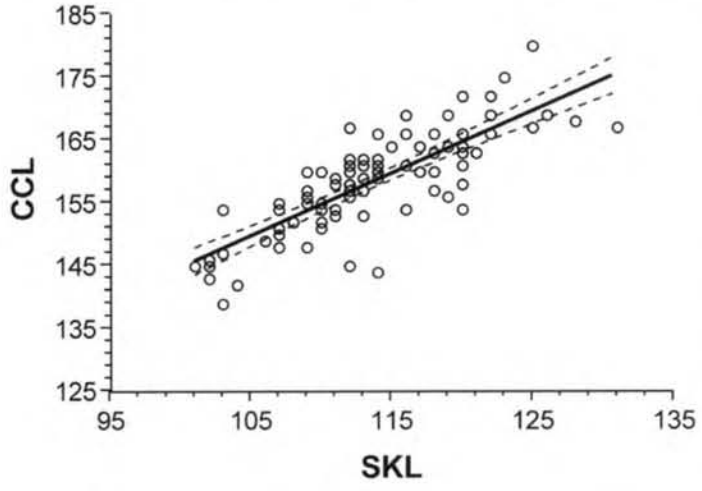

FIG. 3. Relationship between curved carapace length (CCL) and left side keel length (SKL) of 91 individual female *D. coriacea* in French Guiana. Simple linear regression analysis is shown by the solid line ($Y = 0.995X + 45.26$; $r = 0.80$), and the two dashed lines bind the 95% confidence interval.

We are grateful to Johan Chevalier, Brendan Godley, and Marc Girondot for comments and suggestions. Support for annual marine turtle research in the Reserve Naturelle de l'Amana comes from DIREN (Guyane), and is administered by SIVU-Amana. GRAPTEMYS GIBBONSI (Pascagoula Map Turtle). **PREDATION**. On 26 September 1999, a ca. 600 g spotted bass (*Micropterus punctulatus*) was caught in Pushepatapa Creek, NW of Hwy 21, in Washington Parish, Louisiana, USA. While cleaning the fish, a small specimen of *Graptemys gibbonsi* (NLU 70484) was dissected from the stomach. The turtle measured 35.6 mm in carapace length and 31.5 mm plastron length. It was a recently emerged hatchling as judged by the presence of an acute ventral flexure of the bridge along the longitudinal seam between pectoral-abdominal and marginal scutes, plus a plastral fontanelle indicating the presence of a fresh umbilical scar at the time of death. Damage to the specimen was limited to the margin of the posterior carapace where peripheral bones and/or marginal scutes were missing from ca. marginals 6–9 on the left and 4–12 on the right. Costal scutes 3 and 4 on the right were also missing.

There are no previous reports of specific predators for any life stage of this species (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, DC. 578

pp.). Predatory fish such as bass have only infrequently been reported to eat hatchling turtles (Semlitsch and Gibbons 1989. Copeia 1989:1030–1031; Britson and Gutzke 1993. Copeia 435–440); however, it is not possible to state whether the specimen reported here was ingested alive or dead. Both studies reported that *Micropterus salmoides* (largemouth bass) eat dead hatchling turtles, but not live ones. The presence of the hatchling in a fish at this location indicates that there is nesting along Pushepatapa Creek by *G. gibbonsi*, and that nest emergence occurs in late summer-early fall.

We thank Randy Lanctot for saving the specimen and depositing it in the Museum of Natural History.

CROCODYLIA

CAIMAN LATIROSTRIS (Broad-snouted Caiman). **COMMUNAL NESTING**. Communal nesting is described for many squamates (e.g., Capula and Luiselli 1995. Herpetol. Rev. 26:38; Rand 1968. Copeia 1968:552–561; Shanbhag 1999. Herpetol. Rev. 30:166; Swain and Smith 1978. Herpetologica 34:175–177), but little is known about this behavior among crocodilians. Yanosky (1990. Revue Fr. Aquariol. 17:19–31) mentioned communal nesting in *Caiman latirostris*, but did not detail his evidence. Here, I describe evidence for communal nesting in *C. latirostris* from Estancia El Lucero in the northern part of Departamento San Cristobal, Provincia de Santa Fe, Argentina.

During harvest of caiman eggs for Proyecto Yacare in the unusually dry season of January 2000, I discovered a small (ca. 1 ha) lagoon within a dense bulrush (*Scirpus*) and cattail (*Typha*)-dominated marsh 8 km N Estancia El Lucero (29°54'43"S, 60°50'36"W). This lagoon was the only body of water within 20 km. During my survey of the lagoon, I found 23 *C. latirostris* nests scattered in its floating vegetation that contained a total of 879 eggs. Three of these nests exhibited evidence of oviposition by more than one female: egg numbers were higher than clutch sizes reported for *C. latirostris*, clusters of eggs of at least two different sizes were present, and nests were at least partly divided into two or more chambers. Two of the three nests had 59–67 eggs, two different sizes of eggs, and partial division of the nest into two chambers. The remaining nest had 129 eggs, was divided into four chambers, but had a central chamber with eggs of different sizes, some of which were broken. These data suggest that 2 or 4 females created these nests. Clutch size range reported for *C. latirostris* (23–44, mean = 37.1; Larriera 1991. Rev. Asoc. Cienc. Nat. Litoral 22:19–23) is similar to the number of eggs in the other 20 nests I found in the lagoon (19–41; mean = 31.2), which supports the idea that one female made each one. Nests with evidence of communal oviposition did not differ substantially in size and shape from remaining *C. latirostris* nests.

I thank Marc P. Hayes for his suggestions on the manuscript.

Submitted by **ALEJANDRO LARRIERA**, Proyecto Yacare (CONVENIO MAGIC/MUPCN), Pasaje Privado 4455 (Centeno 950), Santa Fe 3000, Argentina; e-mail: yacare@arnet.com.ar.

CROCODYLUS ACUTUS (American Crocodile). **HATCHLING DIET**. Few field studies of hatchling crocodilian diets exist, and the feeding ecology of hatchling *C. acutus* is unstudied. We provide the first report on the diet of hatchling *C. acutus* based on data from Turneffe Atoll, Belize, a ca. 50-km island chain located 35 km E of the mainland.

On 9 July 1997, we captured 26 hatchlings from a black mangrove (*Avicennia germinans*) lagoon (<1 ha) next to a known *C. acutus* nesting beach (Platt and Thorbjarnarson 2000. Copeia 2000:869–873) on Northern Cay (17°29'N, 87°47'W). Despite recent heavy rainfall, salinity (measured with an Atago S-10E® optical refractometer) in the lagoon matched that of seawater (34 ppt). Hatchlings were captured by hand from 2000 to 2230 h with the aid of a headlamp. Two adult crocodiles also present in the lagoon did not respond to distress calls of hatchlings during the latter's capture. Hatchlings were measured (total length [TL]; snout-vent length [SVL]; and head length [HL]: measured dorsally from the tip of snout to median posterior edge of the cranial roof), permanently marked by notching a unique series of caudal scutes, and then released at the capture site the next night. Mean (± SD) hatchling morphometrics were: TL = 28.8 ± 1.0 cm (range = 26.2–34.0 cm); SVL = 13.7 ± 1.0 cm (range = 12.4–16.3 cm); HL = 4.3 ± 3.1 cm (range = 3.9–5.0 cm); HL/SVL ratio = 0.31 ± 0.004 (range = 0.30–0.32). Based on presence of an egg tooth and open umbilical scar, 20 of the hatchlings were probably < 7 days old; the remainder were estimated at 7–21 days old.

Stomach contents were flushed using a modification of the technique Taylor et al. (1978. J. Herpetol. 12:415–417) described. A flexible plastic tube (30 cm long; 5.5 mm exterior diameter) lubricated with vegetable oil was eased down the esophagus and into the stomach. Water (ca. 4 cc) was slowly poured into the tube until the abdomen distended visibly. Gently palpating the abdomen caused a mixture of water and stomach contents to surge into the tube. The hatchling was then inverted and the mixture directed across a fine mesh screen. The process was repeated (usually 3–4 times) until only water free of stomach contents was observed.

We recovered prey items from 18 (69%) hatchlings; six of 20 (30%) hatchlings < 7 days old and two of six (33%) older hatchlings had empty stomachs, indicating that neonates initiate feeding within a week of hatching. Similarly, Platt (1996. The Ecology and Status of Morelet's Crocodile in Belize. Dissertation, Clemson University, Clemson, South Carolina) found hatchling *C. moreletii* began feeding 4–7 days post-hatching, and prey items have been recovered from 1–2-day-old *Caiman crocodilus* (JBT and T. Escalona, unpubl. data). Hatchling *C. acutus* with empty stomachs were not included in our dietary analysis. Stomach flushing suggests that hatchling *C. acutus* feed mostly on invertebrates. Insect remains were recovered from 12 (67%) hatchlings and consisted primarily of highly macerated bits of chitin and fleshy material unidentifiable to taxon, although one contained parts of a beetle (Coleoptera). The stomach contents of five (27%) hatchlings contained crustaceans, probably fiddler crabs (*Uca* sp.), which were abundant along the shoreline. Thorbjarnarson (1988. Bull. Florida State Mus., Biol. Sci. 33:1–86) found fiddler crabs to be the most important prey of juvenile (TL < 0.5 m) *C. acutus* in Haiti. A partially digested fish (length = 13.5 mm) recovered from one (5%) hatchling was the only vertebrate found among the stomach contents we examined. We expected higher levels of fish

consumption as this might be an important way for hatchling *C. acutus* to behaviorally osmoregulate in saline environments (Thorbjarnarson 1989. *In* P. M. Hall [ed.], Crocodiles: Their Ecology, Management, and Conservation, pp. 228–258. IUCN, Gland, Switzerland).

Fischer et al. (1991. J. Herpetol. 25:253–256) contend that hatchling *Alligator mississippiensis* cannot effectively capture small prey owing to a long snout in relation to body size (Mean HL/SVL ratio = 0.31; S.E. = ± 0.001; N = 288), and instead rely on metabolizing residual yolk as an energy source. However, no significant difference exists between the HL/SVL ratio of *C. acutus* and *A. mississippiensis* hatchlings (ANOVA; $F_{1,312} = 0.002$; $P > 0.05$), and the prevalence of prey remains among stomach contents indicates *C. acutus* neonates are adept predators, which begin feeding within 7 days of hatching. Therefore, failure of *A. mississippiensis* hatchlings to capture small prey might not be because of morphological constraints.

CROCODYLUS INTERMEDIUS (Orinoco Crocodile). **AGE AT FIRST REPRODUCTION.** Hunting pressure has extirpated or nearly extirpated many crocodilian populations. As a consequence, conservation efforts in many countries have focused on both protecting land and head-starting wild-caught or farmed neonates which are then reintroduced to protected areas. Orinoco crocodiles, *Crocodylus intermedius*, were nearly extirpated in the Venezuelan llanos prior to a ban on their commercial harvest during the 1970s (Muñoz and Thorbjarnarson 2000. J. Herpetol. 34:397–403; Thorbjarnarson 1992. Crocodiles: An Action Plan for their Conservation, IUCN/SSC. 136 pp.). Since 1990, conservation efforts have resulted in the release of > 1300 juveniles in protected private and public lands (C. Chávez, pers. comm.). To date, only modest efforts have been devoted to assessing success of reintroduced individuals. Available data show that animals survive and remain in protected areas (Muñoz and Thorbjarnarson, *op. cit.*), but whether re-introduced individuals were reproducing was uncertain. Here, we document the successful nesting of reintroduced crocodiles in two large cattle ranches located in Distrito Muñoz, State of Apure, Venezuela (7°30'N, 69°18'W).

Both ranches, Hatos El Frío (80,000 ha) and El Cedral (54,000 ha), are located in the flooded savannas of the Venezuelan llanos that previously harbored *C. intermedius*, where hunting pressure had locally extirpated the species (Arteaga and Hernandez 1996. Proceedings of the 13th Working Meeting of the Crocodile Specialist Group, pp. 207–222, IUCN). In 1990, an initial group of 31 juveniles 1–4 years of age was released in Hato el Frío. In 1994, five juveniles were released in Hato El Cedral; four of these were born in 1993 (sizes ranging roughly from 60 to 80 cm in total length) and the remaining juvenile was between 3 and 5 years old. These reintroduced juveniles were regularly observed, but lack of appropriate nesting habitat in the near vicinity limited opportunities for reproduction. As a result, from 1996 to 2001 management built artificial nesting sites. These artificial sites consisted of ~1 m^3 holes excavated in the edges of the water bodies that were filled with river sand from beaches where *C. intermedius* had nested historically.

In March 1998, we found the first two nests (52 and 56 eggs) with fertile eggs. The females that laid these clutches were not captured, so their age is uncertain; however, this site had animals up to 12 years old. In March 2001, at least two of the females released in El Cedral laid eggs. Clutch fertility (30+ eggs in one case; predators destroyed the other nest) could not be assessed because ranch workers mistakenly removed the eggs and they were not incubated for any length of time.

Females that laid the eggs at El Cedral were not caught, but the only *C. intermedius* present were from the 1994 release. Thus, minimum reproductive age for females is no greater than 8 years because only one older *C. intermedius* was known to be present and two clutches were laid. Two of the released females caught in January 2001 were 322 and 342 cm total length, and weighed 145 and 175+ kg, respectively.

Some release sites selected for *C. intermedius* have been on public lands protected only on paper (Arteaga and Hernandez, *op. cit.*; Muñoz and Thorbjarnarson, *op. cit.*). Fishing and poaching have resulted, at best, in limited success for such public land re-introductions. Our data show that re-introductions on private lands where systematic protection is enforced can be successful, at least over a few years. Continued investigation of this promising pattern is needed to determine whether it will continue.

Estacion Cientifica Amigos de Doñana, Available Light, The National Geographic Society, and Association for Conservation Research and Education provided funding and logistic support; COVEGAN allowed us to work on their ranch; and Mauricio Urcera, Jose Ayarzaguena, Tulio Aguilera, Carlos Chávez, Pedro Azuaje, and John Thorbjarnarson helped in data collection .

LACERTILIA

ANOLIS QUERCORUM (Gray Anole). **GENERAL ECOLOGY.** An unfortunate consequence of the huge diversity in the genus *Anolis* (> 300 spp.; Guyer and Savage 1986. Syst. Zool. 35:509–631) is that ecology of many species is unknown. Sparse knowledge for anoles is marked in México, where few taxa have been studied (e.g., Ramírez-Bautista and Vitt 1997. Herpetologica 53:423–431). Here, we address this gap through provision of a few data on the infrequently observed anole *Anolis quercorum*, a species for which no data have become available since its description from Nochixtlán, Oaxaca, México (Fitch 1978. Contrib. Biol. Geol., Milwaukee Pub. Mus. 20:1–15).

Over 4 days (14 May, 12 July, and 2 and 22 September 1998), we collected six *A. quercorum* (four females [field numbers: JLE 3004-5, 3024; and LOL 014] and two males [JLE 2551 and LOL

015]) in the town Zapotitlán de las Salinas, Puebla, México (19°07'19"N, 97°19'24"W) at 1420 m elevation. Vegetation consists of patchwork remnants of thorn forest, xerophilic brushland, and deciduous tropical forest (Rzedowski 1978. Vegetación de México. Editorial Limusa, México) heavily altered by human activities. All anoles were reproductively active adults caught on sunny days between 1300 and 1830 h. They were captured on or under rocks, a dead cactus (*Neobuxbaumia tetetzo*), or a dry "mesquite" tree (*Prosopis laevigata*). Shortly after a heavy rain at dusk on 22 September, we observed male LOL 015 attempt to court female LOL 014 from 1730 to 1830 h. Both anoles were perched in a mesquite tree. The male was facing downward ca. 2 m above the ground, and flashing his dewlap at the female located 1.25 m away and 0.75 m below the male. The female ignored the male despite his continued advances, and ultimately fled to a remote part of the tree. After 35 min of courting attempts by the male, the female jumped to a nearby rock heap, and concealed herself. The male then positioned himself in front of the rock heap for ~15 min, but then returned to the tree, where he again began flashing his dewlap.

We thank Hobart M. Smith for providing literature; Felipe Correa, Guillermo Woolrich, Jorge González for their assistance in the field; Julio Lemos for allowing us to use specimens the third author (VMS) collected; Marc P. Hayes for suggestions; and the Dirección General de Apoyo al Personal Académico (Proyecto No. IN208398) for funding.

ANOLIS SMALLWOODI (Chipojo). **FOOD HABITS**. Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions and Natural History. Univ. Florida Press, Gainesville. 720 pp.) note that in captivity *Anolis smallwoodi* consumes plant matter, meat, other anolines, and house mice. However, no reports on the diet of *A. smallwoodi* under natural conditions exist. Here, we provide the first field report of *A. smallwoodi* diet.

On 12 September 1999, we witnessed an adult *A. smallwoodi* (ca. 150 mm SVL) eating a juvenile (ca. 45 mm) Cuban treefrog, *Osteopilus septentrionalis* (Hylidae), in the Botanical Gardens of Santiago de Cuba. The lizard sat on the shaded branch of a Salvadera tree (*Hura crepitans*) 8 m above the ground. When first observed at 1000 h, the anole had grasped the hindquarters of the frog, and the latter was emitting squeaks similar to those when it is being swallowed by a Cuban racer, *Alsophis cantherigerus* (see Buide 1985. Reptiles de Cuba, Gente Nueva, La Habana, 90 pp.). For ca. 1 h, the anole tried to swallow the frog, shaking it vigorously and striking it against the branch until the frog stopped moving or vocalizing. For another hour, the lizard kept repositioning the frog in attempts to swallow it. Finally around 1200 h, the *A. smallwoodi* swallowed the frog. During the 2 h of prey handling, the anole changed position several times, switched branches, went up and down ca. 40 cm in the tree, but always remained in the shade.

This is the first record of *A. smallwoodi* consuming an anuran. Some giant anoles are known to prey on vertebrates (Losos et al. 1991. Caribb. J. Sci. 27:173–179), such as amphibians, anoline lizards, and birds. Nevertheless, among Cuban giant anoles, only *A. equestris* has been reported to feed on *Osteopilus* (Schwartz and Henderson, *op. cit.*). The lengthy prey handling interval may indicate that *O. septentrionalis* is infrequent prey for *A. smallwoodi*.

We thank Iliana Boza for helping with the English translation and Renata Platenberg for her review.

ANOLIS SMALLWOODI SMALLWOODI (Chipojo). **MAXIMUM SIZE.** The reported maximum size (as SVL) for *A. smallwoodi smallwoodi* is 158 mm for females and 172 mm for males, both from Sierra Maestra in eastern Cuba (Schwartz 1964. Bull. Mus. Comp. Zool. 131:403–428, Schwartz and Garrido 1972. Stud. Fauna Curacao Caribbean Isl. 134:1–86). Here, I report on a larger individual also collected in eastern Cuba.

At 1430 h on 8 December 1996, Leopoldo Viña collected a female *A. smallwoodi* from the branch of shrub 2.5 m above the ground in a garden in the village of El Modelo, El Caney, Santiago de Cuba Province (20°02'46"N, 74°46'40"E). This female *A. smallwoodi smallwoodi* was 177 mm SVL (tail = 325 mm, mass = 155 g), which exceeds the previous record for the species by 5 mm, and for females by 19 mm. The specimen (BSC.H 828) was deposited in the herpetological collection of the Centro Oriental de Ecosistemas y Biodiversidad (BIOECO) in the Museum of Natural History "T. Romay".

I thank Leopoldo Viña for donating the specimen, John E. Cadle for providing key literature, Iliana Boza for helping with the English translation, and Renata Platenberg for her review.

EGERNIA STOKESII (Gidgee Skink). **OPPORTUNISTIC DISPERSAL.** In the Flinders Ranges of South Australia, *Egernia stokesii* occupy crevices in isolated rocky outcrops (Gardner et al. 2001. Mol. Ecol. 10:175–183). In these outcrops, we have recorded *E. stokesii* family groups of up to 17 lizards forming stable aggregations that can persist for over five years. Multiple groups can be found in an outcrop, group members share small home ranges, and dispersal is relatively rare (Gardner et al., *op. cit.*). Some lizards that occupy crevices on the edges of family group territories, termed floaters, may have greater opportunity for dispersal. Here we report on the car-mediated opportunistic dispersal of a male floater, recorded during our six-year (1992–98) study of 17 family groups occupying a single 1.5-ha outcrop,

Camel Hill, near Hawker (31°53'26"S, 138°25'24"E), South Australia.

We first recorded and individually marked a male *E. stokesii* (182 mm SVL) on the Camel Hill outcrop during the 1995–96 field season, when it occupied marginal crevices in the abutting territories of two stable family groups. Undetected during the 1996–97 field season, we recaptured this male in May 1997 (two months after completion of fieldwork) in the engine of GAD's car in Adelaide, 500 km S of the study area. The car had been regularly parked at a location 350 m from the outcrop. We inferred from deposited scats and scratch marks in the oil that the lizard had occupied the engine for some time. The front grill of the car had accumulated numerous grasshoppers over the previous summer. Scat deposits contained grasshopper remains. Crevice-like aspects of the engine structure and/or presence of grasshoppers on the grill may have induced this male *E. stokesii* to take up residence in the car's engine.

After being kept over winter in Adelaide, we released the male *E. stokesii* the following spring (September 1997) in a crevice it previously had occupied on the Camel Hill outcrop. We recaptured it on the outcrop in October 1997, but it moved to a rock pile 300 m north of Camel Hill in the same month, and was not subsequently seen.

Our observation indicates that opportunistic transport can result in the movement of *E. stokesii*, and that this form of dispersal, albeit rare, may provide opportunities for range expansion. We thank the Australian Research Council for supporting this research.

HELODERMA SUSPECTUM (Gila Monster). **EGG PREDATION BY JUVENILES**. Highly specialized, wide-ranging foraging for patchily distributed vertebrate nests (e.g., newborn mammals in their burrows, ground-nesting bird eggs and nestlings, and tortoise eggs) is a well-documented aspect of the life history of adult *Heloderma suspectum* (Beck 1990. J. Herpetol. 24:56–68; Jones 1983. Herpetologica 39:247–253; Porzer 1981. Movement, Behavior, and Body Temperature of the Gila Monster, *Heloderma suspectum* Cope, in Queen Creek, Pinal County, Arizona, Masters Thesis, Arizona State Univ., Tempe. 100 pp.). However, no published studies to date have addressed the diet of juvenile Gila monsters, which are rarely observed in the wild. Lowe et al. (1986. The Venomous Reptiles of Arizona, Ariz. Game and Fish Dept., 115 pp.) and Brown and Carmony (1991. Gila Monster: Facts and Folklore of America's Aztec Lizard, High-Lonesome Books, New Mexico, 127 pp.) refer to the ability of "young" Gila monsters to consume 50% of their body weight, but the age, size, diet, and status (captive or wild) of the *H. suspectum* supporting their statements was not reported. Accordingly, I provide here the first report of juvenile Gila monster diet in the wild.

I removed the stomach contents of two juvenile *H. suspectum* salvaged as road-kills in Arizona. Both of these specimens, along with four of six reptile eggshells in their stomachs, are deposited in the California Academy of Sciences (CAS). I salvaged the first (CAS 212926: 130 mm SVL, 66 mm TL) as a fresh kill on 3 August 1996 at 0714 h on U.S. Hwy I-10 frontage road 0.6 mi E State Hwy 83 (~20 mi SE Tucson), Cochise Co. The small size of this specimen is notable as it falls within the range of captive-hatched neonates (Peterson 1982. Herpetol. Rev. 13:122–124; unpubl. SVL data for 43 neonates: mean = 127 mm; range = 108–143 mm). Three reptile eggs and a small amount of mammal hair were retrieved from its digestive tract. Measurements of the eggshells inflated with water prior to preservation were 17.0 x 11.5 mm, 17.0 x 11.5 mm, and 18.3 x 11.5 mm. The second juvenile (CAS 212927:175 mm SVL, 88 mm TL) was salvaged as a fresh kill by Brendan McGraw on 17 August 1990 at 2056 h on State Hwy 96 at MM 6 between the towns of Hillside and Bagdad, Yavapai Co. I also removed three reptile eggs from this specimen. Shells of two of the eggs measured 18.0 x 12.5 mm and 20.0 x 12.5 mm (the third egg was not precisely measured but was the same size as the other two). In each specimen, all eggs were in the same initial state of digestion, suggesting that they were consumed as a group. If the two sets of three eggs represent an entire clutch, their size, shape, and number indicate that they are likely to be lizard eggs, perhaps those of *Cnemidophorus tigris* (Fitch 1970. Univ. Kansas Mus. Nat. Hist. Publ. 52:1–247; Fitch 1985. Univ. Kansas Mus. Nat. Hist. Publ. 76:1–76; BMM, unpubl. data).

Reptile eggs, typically deposited in well-concealed, often subterranean locations, are presumably widely distributed in the wild. The difficulty in locating such prey testifies to the well-developed sensory capability of Gila monsters at an early age, a capability previously only documented in adult *H. suspectum*. These stomach contents also show that the widely foraging strategy of adults to prey on nests also extends to juvenile Gila monsters.

Specimens were collected under authority of Arizona Game and Fish Department Scientific Collecting Licenses SP655335 (CAS 212926) and SP780427 (CAS 212927).

LEIOCEPHALUS MACROPUS (Bayoya). **SAUROPHAGY**. *Leiocephalus macropus* is a moderate-sized (75–95 mm SVL) terrestrial lizard (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions and Natural History. Univ. Florida Press, Gainesville. 720 pp.) that feeds primarily on invertebrates (insects, spiders, centipedes, and mollusks), but also consumes plant material, mainly flowers (Sampedro et al. 1979. Cien. Biol. 3:129–139). Saurophagy and cannibalism had been reported for other generally larger Cuban species of *Leiocephalus*—*L. carinatus* (Martínez and Rodríguez 1987. Misc. Zool. 29:1–2), *L. stictigaster* (Martínez et al. 1990. Poeyana 403:1–18), and *L. cubensis* (Martínez and Fernández 1994. Cien. Biol. 26:21-29; Milera 1984. Misc. Zool. 22:2)—but never for *L. macropus*. Here, we provide the first report of saurophagy in *L. macropus*.

During a recent study of the trophic ecology of lizards of Eastern Cuba, two adult (67 and 68 mm SVL) male *L. macropus* were collected at Siboney, Santiago de Cuba on 10 March 1998. Both individuals were collected as they were climbing on rocks in xeric coastal shrub (Capote and Berazaín 1984. Rev. Jardín Bot. 5:1–49). Examination of the gastrointestinal tract of the larger male

revealed an adult *Anolis jubar* (40 mm SVL, 1.66 g mass) and several insects, principally ants and beetles. *Anolis jubar* is an abundant lizard in Siboney, commonly found on the ground and at the base of tree trunks (Castillo 1998. Partición del Nicho Ecológico en la Comunidad de Saurios de la Reserva Natural Siboney, Santiago de Cuba. Tesis de Licenciatura, Santiago de Cuba). These characteristics and the fact that *L. macropus* forages on the ground would potentially make *A. jubar* relatively accessible prey for *L. macropus*.

We thank Rolando Viña for field help, Iliana Boza for the English translation, and Renata Platenberg for her review.

Romay," Enramadas # 601, Santiago de Cuba 90100, Cuba (e-mail: ansel@bioeco.ciges.inf.cu), and **E. B. DEL CASTILLO**, Departamento de Biología, Universidad de Oriente, Santiago de Cuba, Cuba.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **NOCTURNAL NESTING, EGGS, NEST PREDATION, HATCHLINGS.** In reporting nocturnal nesting of *Phrynosoma modestum* (Sherbrooke 2000. Herpetol. Rev. 31:242–243), I reviewed nesting reports of *P. cornutum,* which included diurnal and nocturnal observations. Between 29 May and 1 June 2000 three female Texas horned lizards (that later nested) were road collected in the Playas Valley, Hidalgo Co., New Mexico, USA (Sherbrooke 2002. Herpetol. Rev. 33:21–24). Snout–vent length (SVL) and mass were as follows (in sequence of lizards presented below): 88 mm, 40.7 g; 103 mm, 66.3 g; 104 mm, 68.5 g. They were maintained with other *P. cornutum* in captivity at the Southwestern Research Station, Portal, Arizona, in an outdoor screened cage, 7.0 x 3.8 x 2.4 m. Animals were fed seed-harvester ants (*Pogonomyrmex* spp.; Sherbrooke 1995. Herpetol. Rev. 26:25–26) and crickets (*Acheta domesticus*) daily, and provided with water by hose sprinkler and natural rainfall for "rain-harvesting" (Sherbrooke 1990. J. Herpetol. 24:302–308). While held in captivity all three females gained weight from time-of-capture mass. Nest sites, nesting activities, and hatchling emergence were photographed.

On 25 July (0730 h MST) a group of 24 *P. cornutum* was moved from the holding cage, where the soil was compact clay, to an identical unit in an animal behavior observatory that had looser and sandier soil, and an alternately-arranged pattern of artificial "shrubs" of *Ephedra trifurca* branches (70 cm high) and groups of four rocks (5 cm diam), spaced at 1 x 0.75 m. Lizards were numbered (18 point type) dorsally with glued-on white paper tags. Two females proved to be gravid; 25 July mass of each was 53.3 g and 71.0 g. Previous rainfall in July was 2.7 cm, with 1.4 cm falling 16 July, and early-evening trace amounts falling on 23, 25, and 26 July. On 29 July 0.4 cm of rain fell. Daily 24-hour high and low temperatures (between 1700 h) were as follows: 24–25 July 32.7/13.3°C; 25–26 July 32.7/15.0°C; 26–27 July 32.9/18.3°C.

At 2045 h on 25 July one female was discovered digging a nest in the moist soil midway between a shrub and rock site. She was completely underground in the slanted tunnel (in further than 5 cm). Freshly-dug soil was scattered at the surface. The following morning (26 July; 0730 h) the filled-in tunnel was covered to the surface where the female was resting. The soil covering the entrance was distinct from the surrounding soil. A coin was placed on the entrance site. By 1030 h the surface had been covered with scattered pebbles, matching the texture of surrounding areas, and the penny was buried from view. The lizard, sitting under a shrub when I entered the cage, moved toward the nest, a behavior repeated when I again entered at 1300 h. On 28 July this female weighed 32.3 g, having lost 21.0 g (39.4% of pre-laying body weight).

At 2100 h on 26 July a second female in the same group and cage was found digging a nest in moist soil midway between a shrub and rock site. At 2200 h she was actively working underground, but with her tail and hindquarters visible. By six hours later (0400 h; 27 July) she had laid her clutch of eggs and refilled most of the soil in the tunnel to within 5 cm of the opening. She was still working at this task. Facing away from the tunnel, she raked soil behind her, with front and hind legs, into the remaining entrance of the tunnel and then turned 180° to face into the depression. Then she repeatedly head butted the soil so as to compactly fill the cavity. By 0515 h the underground/covered tunnel was filled in, but the female was still below the surface level in the indentation leading to the tunnel. At 0715 h she was in final stages of covering the depression with surface sand and gravel when a light rain started. At 0930 h scratch marks were noted in areas adjacent to the former entry indicating where surface materials had been removed to disguise the nest. On 28 July this female weighed 40.1 g, having lost 30.9 g (43.5% of pre-laying body weight).

The morning of 31 July both nest sites were excavated for examination of nest tunnel form, and egg recovery. The former tunnel entrance of the first nesting was oriented toward the north-northwest. The delicate eggs were 16 cm down the soil-filled tunnel, with the uppermost layer of eggs at 12 cm deep. Eggs were tightly packed with damp sandy soil in a terminal oval chamber which measured 2.5 cm deep and 5 cm across. Twenty eggs were recovered, four of which were broken; several more leaked tiny amounts of fluid. The orientation of the opening of the second nesting had also been toward the north-northwest. The former-tunnel channel sloped downward for about 10 cm before reaching the top of a spherical terminal chamber, 4 cm deep and 5.5 cm across. The uppermost eggs, tightly packed in moist soil, were 12 cm below the soil surface. The 40 eggs were arranged in three to five layers, all in very close proximity to each other. Three eggs were damaged and not weighed.

Of the first clutch, 16 eggs were weighed: mean = 1.16 ± 0.05 SD g/egg. Using the mean-egg-weight for the four unweighed eggs, the estimated mass of the 20-egg clutch was 23.14 g. This was 2.14 g more than the laying-associated weight loss (21.0 g) of the female, indicating a clutch weight gain of 9.2% (apparently due to water uptake and soil adhesion).

Thirty-seven of the second-clutch eggs were weighed: mean = 0.87 ± 0.05 SD g/egg. Using the mean-egg-weight for the three unweighed eggs, the estimated mass of the 40-egg clutch was 34.89 g. This was 3.99 g more that the laying-associated weight loss (30.9 g) of the female, indicating a clutch weight gain of 11.4% (seemingly because of water uptake and soil adhesion).

A third female was fitted with a Holohil PD-2 radiotransmitter (3.4 g; 148 kHz, pulse 0.6 sec; whip antenna 16 cm; glued to the

central back with clear silicone and sprinkled with soil for background camouflaging) and released 12 July 2000 (1130 h; lizard mass 75.6 g) in Chihuahuan Desert habitat 5 km E of Portal, Arizona, in the San Simon Valley. During the subsequent five days the lizard was relocated 2–3 times/day (13 times).

When located at 2135 h (air temperature, AT 27°C) on 14 July the lizard was in the process of excavating a cavity in moist soil into which its head and body had entered, but into which it did not disappear from view. The lizard removed soil with its hind feet while digging with its forefeet. Later, when revisited at 2330 h there was only minimal progress on enlarging the cavity. The next morning (15 July) at 0930 h (AT 31°C) the lizard was found in the shade of an *Acacia constricta* one meter from the cavity entrance. The east-facing opening was 3–4 cm high, 7 cm wide, and 12 cm deep, with a notch in the roof apparently worn by the radiotransmitter package. At 1320 h (AT 35°C) the lizard was 2 m from the cavity at the base of an acacia shrub, and the cavity, with a pile of soil at the entry, appeared undisturbed since morning. That night, at 2140 h (AT 24°C), the female was back digging in the nest, at times entirely underground. The following morning (0900 h; AT 28°C; 16 July) the lizard was encountered standing high on stretched legs while facing the sun from on top of the former-cavity entry, now completely filled and covered with soil. By 1330 h (AT 31°C) the nest-cavity site had been raked over with small pebbles, as had two or three places up to 0.75 m away; the lizard was 2 m away in the shade of a shrub. Heavy rain fell at 1400 h. At 2125 h (AT 24°C) the female was sleeping 4 m from the nest under an acacia shrub, and the following day (17 July) by 1330 h she was 100 m away. Later (2205 h), she was recaptured, still distant from the nest site. This lizard's mass on 18 July (0700 h) was 42.2 g, with a weight loss of 33.4 g (44.2% of pre-laying body weight). Nesting was accomplished over a two-night period, with intervening cessation of digging activities during the heat of day.

On 29 July (0710 h) this desert nesting site was revisited and found to have been disturbed (and predated). When excavated, the tunnel cavity was found to be 22 cm long. Seven eggs (five of which were damaged during removal) were located 10 cm below the surface; weights of two intact eggs were both 1.09 g. Based on female loss of body mass (in laying eggs) and increased weights of eggs hydrated in nests (see two captive females above), I estimate that eggs gained 10% in mass after laying (10% above female body-weight loss). Thus, this radiotelemetered female, having lost 33.4 g in laying, must have had a nest clutch weighing 33.4 + 3.3 (10% gain) = 36.7 g. With an egg weight of 1.09 g for recovered nest eggs, the unpredated clutch size is estimated to have been 33.7 (probably 34) eggs. The disturbance characteristics of the nest site (a narrow hole) by the predator and its extraction of eggs from the long tunnel cavity suggests that an ophidian predator consumed 27 eggs, 79.4% of the clutch.

Considering the SVLs of the three gravid females (88, 103, and 104 mm), the smallest lizard laid the lowest percentage of its body weight as percent body-mass lost (39.4%, 43.5%, and 44.2%), and the smallest female laid the smallest clutch of eggs (20 vs. 40 and 34-estimated).

Eggs of the three females were placed on dampened vermiculite (50% distilled water by weight) in glass bowls inside clear plastic bags (Zweifel 1961. Copeia 1961:112–113) and incubated at 23.3–33.3°C. Two eggs (of the remaining four) of the field-predated nest hatched 21 September 2000, after 68 days; the remaining two eggs had molded. Hatchling masses were 0.81 and 0.83 g; dry shell masses were 0.05 and 0.07 g. The same day four eggs (N = 16 incubated, of 20), from the first cage-nesting female, hatched 59 days after laying. Five more eggs of this clutch hatched the following day, and the final seven eggs hatched on the next day, 23 September. Included in these successfully incubated eggs were several that had leaked some egg fluid when removed from the nest site. Hatchling mass was mean = 0.87 ± 0.07 SD g, and shell mass was mean = 0.04 ± 0.02 SD g.

On 23 September the eggs (N = 36 incubated, of 40) of the second cage-nesting female were moved, in anticipation of hatching, from the incubation chamber into the bottom of a glass aquarium (15.5 x 51 x 31 cm high) where they were arranged in a single-layer, six-eggs x six-eggs square pattern, 6 cm across. More than half of the eggs leaked fluid as a result of handling. Eggs were covered with 8 cm of moist, sandy soil. The tank was usually placed in the sun during the day, and indoors at night. On 25 September at 0600 h several eggs had started hatching, 62 days after being laid. They were seen through the glass bottom of the tank. On the 26th and 27th of September additional hatching movements were noted. A hardened evaporation-soil-crust had formed by the early morning of the 28th and this was broken up and removed, thus reducing the soil-cover depth to 6.5 cm. One emerging hatchling was uncovered in the process. Hatchlings continued appearing at the surface throughout the afternoon and evening (1200–2200 h), and by 0630 h on 29 September 32 hatchlings had emerged via seven exit holes (4.57 hatchlings/hole). Up to four hatchlings simultaneously occupied an expanded exit-hole opening before fully emerging onto the soil surface. The exit holes covered an area 6 x 10 cm. Twenty-one of the surfaced hatchlings (N = 32) had egg teeth; in 11 hatchlings egg teeth were missing. Of those egg teeth in place, some were loosely attached, and some were still tightly attached. At 1400 h (30 September) the remaining unemerged eggs were excavated. They were located at the bottom of the soil, on the aquarium glass. All four hatchlings had partially emerged, one its head only, and three with head and front legs emerged. Three were dead (and partially deteriorated), and one was breathing. By 1700 h the live lizard had extricated itself from its shell; its weight (0730 h, 1 October) was 0.61 g, low for its clutch. What its fate would have been if it had remained undisturbed is unknown. But, another hatchling of identical mass (the lowest) had emerged earlier to the surface.

The emerged hatchlings were weighed (mean = 0.73 ± 0.05 SD g). Thus the mean mass of each hatchling was 83.9% of the initial (nest) egg mass (mean = 0.87 g). This compares to the 1-day earlier nesting by the smaller female where the mean mass of each hatchling (0.87 g) was 75.0% of mean initial (nest) egg mass (1.16 g). Of the two, the smaller female laid larger eggs which produced larger hatchlings.

Burrow (2000. MS. Thesis, Oklahoma State University, Stillwater. 144 pp.), working with radiotelemetered *P. cornutum* in southern Texas, found seven nests all dug in the morning and concealed by evening or the following morning (no night observations). Nests were located under shrub clumps, where herbaceous vegetation was absent. Nests were usually dug straight down and later turned 90 degrees. The three Arizona nestings of *P.*

cornutum reported here, also another nesting of *P. cornutum* reported earlier and one for *P. modestum* (Sherbrooke 2000, *op. cit.*), contrast with the southern Texas observations of *P. cornutum* by Arizona nests (1) being located away from shrubs, (2) being dug, oviposited, and covered at night, and (3) being sloped into the soil. Regional climatic conditions or genetic differences might play a role in nesting behavior of *P. cornutum*.

PHRYNOSOMA HERNANDESI (Short-horned Lizard). **SUCCESSFUL OPEN-MOUTHED THREAT DEFENSE.** On 11 April 1988 at 1600 h MST a group of three individually color-banded Mexican jays (*Aphelocoma ultramarina*), part of a resident flock of 18 individuals under study at the Southwestern Research Station in the Chiricahua Mountains of southeastern Arizona, were seen by one of us (ERB) to be mobbing an adult *Phrynosoma hernandesi*. One bird picked up the lizard in its beak and flew to a branch of an alligator juniper (*Juniperus deppeana* Steud.), about 1.5 m off the ground, where all three birds congregated. Shortly the lizard freed itself from the bird and dropped to the ground. The dominant bird (the dominance hierarchy of this flock has been studied) continued pursuit, keeping the other two birds from approaching the lizard. The lizard raised itself up on all four legs, faced the bird and opened its mouth widely (showing red inside; observed with binoculars). Hissing, often exhibited with open-mouthed defensive displays in various species of horned lizards (Sherbrooke 1991. Am. Midl. Nat. 126:187–195; Sherbrooke and Middendorf 2001. Copeia 2001:1114–1122), was not heard, but might have been executed. The defense was successful as the jay, known to eat some lizards (Brown 1994. *In* A. Poole and F. Gills [eds.], The Birds of North America, No. 118:1–16), flew away leaving the lizard (5–10 min after originally seen) apparently unharmed and defensively motionless on the ground. No defensive blood-squirting (Middendorf and Sherbrooke 1992. Copeia 1992:519–527) was observed. On 9 April 1999 a two-year-old juvenile Mexican jay from a neighboring resident flock (a second bird was seen departing) was observed (by Adrienne Smith for 12 min beginning at 1645 h MST) pecking a small-adult short-horned lizard (approximate snout–vent length 70 mm) on a branch while sitting in an alligator juniper. The lizard was held by the bird in its feet and was pecked at vigorously, and later was held in its beak before the bird departed with the dead lizard. One of these observations documents a successful use of a postulated antipredator display, open-mouth threat, against a predatory species. The second observation shows that the Mexican jay can be a lethal horned lizard predator.

PHRYNOSOMA HERNANDESI (Short-horned Lizard). **DEFENSIVE HISS.** On 24 July 1993 a gravid adult female (SVL 78 mm; mass 39.2 g) was collected 5.3 miles S jct. NM Hwy 130 on NM Hwy 6563 south of Cloudcroft, Lincoln National Forest, Sacramento Mountains, 2727 m elev., Otero Co., New Mexico (USA), and brought to Portal, Arizona. When handled this lizard exhibited open-mouth threats and hissed, and on 26–27 July 1993 recordings were made of four hiss sounds at room temperature. Oscillograms and frequency spectrograms were prepared of the four similar hisses; one was selected for illustration (Fig. 1). Open-mouthed threats and hissing have been reported in several species of *Phrynosoma* (Carpenter and Ferguson 1977. *In* Gans and Tinkle [eds.], Biology of the Reptilia Vol. 7, Ecology and Behaviour A. pp. 335–554. Academic Press, London; Sherbrooke 1991. Am. Midl. Nat. 126:187–195), but their audio characteristics have not previously been analyzed.

The recordings were made with a Marantz PMD 430 stereo-cassette tape recorder (flat response to 19 kHz) fitted with a Schoeps CMC-4-UK cardioid response microphone (flat response to 22 kHz; a Sennheiser MZW 201 windscreen protected the microphone) and a customized microphone preamplifier. The tape recording was transferred to a computer via an analogue:digital converter (8bits; 60,000 samples/sec), and the digital signal was filtered (high-pass, set at 200 Hz) and analyzed by appropriate software which also provided the printout.

The hisses ranged from 220 to 228 ms in duration (Fig. 1a), and had frequencies extending from < 0.5 kHz to > 5 kHz (Fig. 1b). This broad frequency range is comparable to that found in the warning sounds (rattling) of rattlesnakes (Young and Brown 1993. Amph.-Rept. 14:373–380; Cook et al. 1994. Herpetologica 50:358–368), which can vary with temperature (Martin and Bagby 1972. Copeia 1972:482–485), and whose characteristics can be assessed by some potential prey of rattlesnakes (Swaisgood et al. 1999. Anim. Behav. 57:1301–1310) and possibly their potential predators.

Hisses and other sounds produced by animals during defensive displays may startle potential predators (Edmunds 1974. Defense in Animals: A Survey of Anti-predator Defenses. Longman Group Limited, Essex. 357 pp.; Young et al. 1999. J. Herpetol. 33:557–566) by engaging an additional sensory modality—an auditory one—in an abrupt fashion so as to trigger reflexive defensive responses. The widespread ability of vertebrate hissing, resulting from exhalation of respiratory air (Gans and Maderson 1973. Amer. Zool. 13:1195–1203), to elicite startle responses suggests its defensive utility. The behavioral context of hissing by horned lizards fits this pattern. One adaptive value of broad-band hisses may be that they are likely to be heard by diverse receivers having different auditory ranges. We suggest that hissing behavior by horned lizards might be one component of a multiple array of displays exhibited in response to approach by particular predators. Moreover, the broad-band frequency characteristics of the hiss (hostile in bird and mammal communications; Morton 1977. Am. Nat. 111:855–869) are similar enough to snake hisses, rattlesnake rattling, and hostile homeotherm acoustic communications as to cause some predators to innately hesitate, thus disrupting subjugation-attack sequences. Functioning thus, hissing might be an antipredatory form of acoustic Batesian mimicry (Rowe et al. 1986. Ethology 72:53–71).

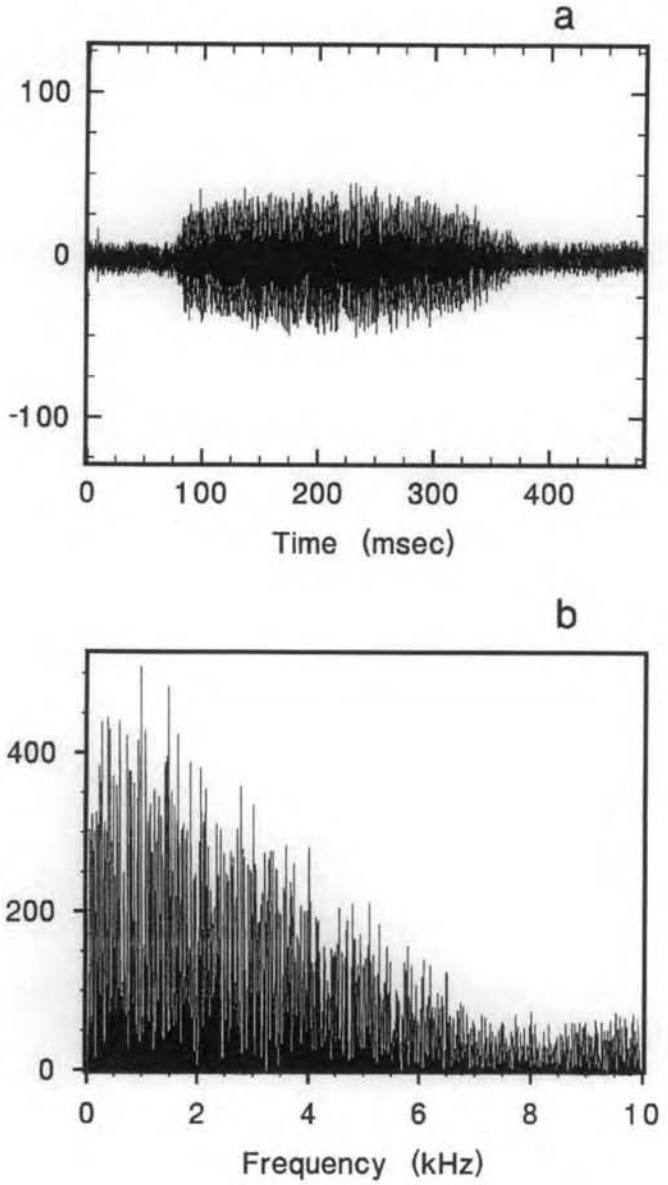

FIG. 1 (a). Oscillogram illustrating energy versus time of *Phrynsoma hernandesi* hiss induced by human handling. (b). Frequency spectrogram of *Phrynosoma hernandesi* hiss induced by human handing. In both (a) and (b) the y-axis is scaled in arbitrary, linear units.

TUPINAMBIS TEGUIXIN (Teiú, Tegu). **DIET**. *Tupinambis teguixin* is reported to have a generalized diet. Foods range from seeds and fallen fruits to a suite of vertebrates (fishes, amphibians, lizards, snakes, birds, and small mammals) and invertebrates (arachnids, gastropods, and insects) (Cei 1986. Monog. IV, Mus. Reg. Sci. Nat. Torino, 527 pp.; Cei 1993. Monog. XIV, Mus. Reg. Sci. Nat. Torino, 949 pp.; Dessem 1985. Copeia 1995:245–247; Duellman 1978. The Biology of an Equatorial Herpetofauna in Amazonian Ecuador. Misc. Publ. 65, Kansas Univ. Press, 352 pp.; Gallardo 1979. *In* W. E. Duellman [ed.], The South American Herpetofauna: Its Origin, Evolution, and Dispersal, pp. 299–307, Univ. Kansas Press; Gudynas 1982. Bull. Chicago Herpetol. Soc. 16:29–39; Martuscelli and Olmos 1996. Herpetol. Rev. 27:21; Norman and Naylor 1994. Amphibians and Reptiles of The Paraguaian Chaco, Vol. I. Privately published, 281 pp.; Rivas et al. 2001. Herpetol. Rev. 32:108; Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. de Ciências Ed., 161 pp.). However, with scattered exceptions the specific identity of vertebrate prey has been rarely provided. Specific-level identity of prey is essential to characterize precisely a species' life history. Here, we provide the first record of amphibian prey for *T. teguixin* identified to species.

On 16 November 2001, we collected a large juvenile (SVL = 329 mm) *T. teguixin* next to the Tocantins River, municipality of Minaçu in the Cana Brava region, Brazil (13°34'11"S, 48°06'49"W). Examination of the stomach contents revealed most of the posterior limbs and pelvic region of an adult *Leptodactylus mystaceus* (femur 24.4 mm; tibia 27.1 mm; tarsus 14.6 mm). *Leptodactylus mystaceus* is a terrestrial frog common in the Brazilian Cerrado, the adults of which frequent vicinity of water in primary or secondary forest (Duellman, *op. cit.*; Rodriguez and Duellman 1994. Guide to the Frogs of the Iquitos Region, Univ. Kansas Press, 80 pp.). Thus, *T. teguixin* has opportunity to encounter this species during its terrestrial foraging.

The *T. teguixin* specimen (CEPB/IFS 227-01) and its anuran prey were deposited in the herpetological collection of the Centro de Estudos e Pesquisas Biológicas at the Universidade Católica de Goiás in Goiânia, Brazil.

SERPENTES

AGKISTRODON CONTORTRIX PHAEOGASTER (Osage Copperhead). **BREEDING**. Records of *in situ* copulations by *Agkistrodon contortrix phaeogaster* have rarely been reported. Fitch (1960. Univ. Kansas Publ. Mus. Nat. Hist. 13:85–288) suggests that copperheads are primarily late spring breeders although there is no set breeding season. The Osage copperhead barely enters Nebraska and is restricted to the extreme southeastern part of the state. Nothing is known about the reproductive season and cycle of *A. c. phaeogaster*.

On 27 August 1998, at 0820 h in Gage County, Nebraska, USA, a pair of Osage copperheads was found copulating. The habitat, located on the west bank of the Big Blue River west of the town of Barneston (T1N, R7E, Sec. 13, SE1/4), can be characterized generally as riparian woodland dominated by cottonwood (*Populus deltoides*) and American elm (*Ulmus americana*). The copulating snakes were located on top of leaf litter in a patch of stinging nettles (*Urtica dioica*). They were observed and photographed for ca. 5 min. before they separated, at which time they were captured and examined. The snout–vent length (SVL) for the female was 53.1 cm and she weighed 157 g. The male measured 73.2 cm SVL and weighed 398 g. The male copperhead was a recapture from

the previous spring and was located 350 m from his emergence den. The ambient temperature was 25.7°C. This is the first report of the reproductive season for Osage copperheads in Nebraska.

COLUBER CONSTRICTOR CONSTRICTOR (Northern Black Racer). **INGESTION OF PLANT MATERIAL**. Incidental ingestion and subsequent passage of plant material by snakes is rarely reported, but might not be an uncommon occurrence in some species (e.g., species that feed in leaf litter, or on prey that have a moist exterior to which debris is likely to adhere). Plant material adhering to ingested prey may generally be of little consequence, but might occasionally pose a threat because of mechanical blockage of the intestine.

On 1 October 2000, we discovered a female black racer (1030 mm SVL, 325 mm TL, 372.6 g mass) beneath a cover board at Shield's Cove at the juncture of Grainger, Union, and Knox counties, Tennessee, USA (36°11'N, 83°42'30"W). We captured the snake by hand and noticed a pine needle (*Pinus taeda*) protruding from the cloaca. The needle was slowly pulled from the cloaca, revealing two additional needles. The first needle broke, was dropped and lost. The two needles left intact each measured 16.1 cm in length and came out tips first, followed by the bundle to which all three needles were attached. As the needles were removed, the snake excreted uric acid as well as an unidentified liquid.

The snake was returned to the Reptile Ethology Laboratory at the University of Tennessee, Knoxville where it was measured, sexed, and weighed, implanted with a PIT tag, and subsequently released to the site of capture.

BURGHARDT**, Department of Psychology, University of Tennessee, Knoxville, Knoxville, Tennessee 37996, USA.

COLUBER HIPPOCREPIS (Horseshoe Whip Snake). **CAUDAL AUTOTOMY**. The ability to shed or to readily lose the tail as a method of escape from enemies is developed to varying degrees in certain salamanders, in tuataras, in many lizards, in some amphisbaenids, in a few snakes, and in certain rodents. Snakes have the most elaborate antipredator mechanisms yet described among reptiles (Greene 1988. *In* Gans and Huey [eds.], Biology of the Reptilia, 16, Ecology: Defense and Life History, pp. 1–152. Alan R. Liss Inc., New York). However, tail autotomy in snakes is a very rare condition. Intervertebral autotomy has been reported in the colubrids *Pliocercus* sp., *Rhadinea decorata, Scaphiodontophis venustissimus,* and *Sibynophis,* all characterized by very long tails (Arnold 1988. *In* Gans and Huey [eds.], Biology of the Reptilia, 16, Ecology: Defense and Life History, pp. 235–273. Alan R. Liss Inc., New York). Herein I report curling behavior and caudal autotomy of *Coluber hippocrepis* under natural conditions.

On 28 October 2000, at Grazalema Natural Park (Cadiz, Spain), I captured a *C. hippocrepis* of ca. 800 mm total length. When I grasped the snake by the tail, the snake quickly and actively curled the body as a screw, transmitting strong pressure to the curled tail at the point where my hand grasped it. After a few seconds, the snake broke off the end of its tail next to my hand and fled. The shed tail (50 mm) moved vigorously for few minutes as happens with autotomized lizard tails.

This species is a medium size snake with a relatively long tail. It is diurnal and when threatened it tries to escape or displays aggressive behavior. A posterior morphological study of 66 *C. hippocrepis* from the collection of the Doñana Biological Station (Sevilla, Spain) showed that tail loss was common in adults of this species and tail autotomy could have contributed to the high rate of tail loss. None of 19 young snakes (< 50 mm SVL) showed any evidence of tail loss. However, 22 of 47 (46.8%) adult snakes (> 50 mm SVL) exhibited some degree of tail loss. These individuals had blunt tails that were usually black. There was no evidence of tail regeneration. Tail curling and tail autotomy have not been previously described for this species. This antipredator response could be very useful when its main predators, diurnal raptors or carnivorous mammals, capture this snake.

CROTALUS CERBERUS (Arizona Black Rattlesnake). **DIET and PREY SIZE**. Herein we report for the first time, to the best of our knowledge, prey of neonatal *Crotalus cerberus* (Coues) (see taxonomic revision in Douglas et al. in press. *In* Schuett, Höggren, Douglas, and Greene [eds.], Biology of the Vipers, Eagle Mountain Publishing, L.C., Eagle Mountain, Utah) and information on prey size. On 30 September 2000, as we inspected dens (hibernacula) and observed denning behavior of *C. cerberus* at several nearby sites ca. 23 km S of Flagstaff, Arizona, USA (Coconino County; 2172 m elev.), we located a neonate at 1545 h, in shade, lying on needles of Ponderosa pine (*Pinus ponderosa*) and partly covered by a cone of the same species. This animal was ca. 50 m W of a den (den entrance was west-facing) used by adult, juvenile, and neonatal conspecifics. Ground temperature was 25°C, air temperature (1 m above ground) was 25.4°C, and relative humidity was ca. 25%.

The noteworthy observation concerning this animal was that it appeared to have recently consumed an unusually large prey item, thus rendering it incapable of rapid movement because of prey size rather than low temperatures. This conclusion was supported by the observation that another neonate (with no conspicuous meal) found 45 min earlier (30 cm off the substrate on a rock ledge ca. 10 m below the den entrance), in shade and exposed to slightly higher substrate (28°C) and air (27°C) temperatures quickly retreated from one of us (GWS) when approached. Palping the neonate revealed that it had consumed a lizard, but attempts to induce regurgitation failed and hence specific identification was not possible. The neonate was collected and retained for further observa-

FIG. 1. Autopsy of a neonatal *Crotalus cerberus* (Coues) found alive on 30 September 2000, and an adult male *Sceloporus undulatus* that it had recently consumed.

tions but died within several hours likely as a result of handling. Prior to dissection, we determined body mass of the neonate (with the prey intact) to be 17 g, SVL was 218 mm, and tail length (to the base of the button) was 17 mm, with only a button present. Sex was female. Upon dissection it was revealed that an adult male *Sceloporus undulatus* had been consumed. Body mass of the prey was 9.05 g, SVL was 68 mm (the snout was partially digested), and length of the tail (fully intact) was 92 mm (Fig. 1). The prey's partially digested snout was positioned at the caudalmost region of the neonate's stomach, its fully intact limbs were adpressed against its body, and its tail was extended cranially (without curvature) in the esophagus. Harry W. Greene verified identification of both species, and they (and Kodachrome slides) are deposited at Cornell University Museum.

Recently, Cundall and Greene (2000. *In* Schwenk [ed.], Feeding: Form, Function, and Evolution in Tetrapod Vertebrates, pp. 293–333, Academic Press, San Diego, California) provided an overview and synthesis of the feeding mechanisms and ecology of snakes, emphasizing in several lineages (e.g., Boidae and Viperidae) the capacity to subjugate and consume bulky prey of extreme relative body mass (Type III prey; prey/predator mass ratios can exceed unity). In our case, the prey/predator mass ratio was 1.138. Importantly, our observation documents that in neonatal *C. cerberus* (a) highly agile prey, such as adult male sceloporine lizards, can be subjugated (presuming the prey was alive) and consumed, (b) first prey in life can be extremely large, exceeding their own body mass, and (c) the capacity to retreat quickly with large, ingested prey is compromised. Consumption of large prey by neonates likely increases vulnerability to predators (or enemies) and critical environmental factors such as low temperatures and inclement weather (for a similar conclusion, see Pauly and Benard 2002. Herpetol. Rev. 33:56–57). Two weeks following the observations of the present neonates the den site was revisited, and at that time (15 October 2000) mid-day air temperature was 14.5°C, and snow showers occurred the following day.

CROTALUS HORRIDUS HORRIDUS (Timber Rattlesnake). **HABITAT**. Records of *Crotalus horridus horridus* using agricultural fields as summer habitat are anecdotal at best (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed. Univ. California Press, Berkeley. 1533 pp.). We report here the use of row crop fields by five *C. horridus* in southern Gage County, Nebraska, USA, during a single-season radiotelemetry study in 1999 (N = 8).

On 1 July 1999, a gravid female *C. horridus* (84.8 cm SVL, 700 g mass) was radiotracked to an alfalfa field. She traveled through the field and eventually took refuge in a pile of discarded wood and metal adjacent to an active hog shed. Although woodland corridors existed, they were ignored as the snake opted for a more direct route through the alfalfa field. On 29 August 1999, this same snake left her refuge and traveled back to her previous location by way of a grazing pasture and a sorghum field, once again ignoring woodland corridors.

Another instance of a *C. horridus* traveling through a row crop field occurred on 21 August 1999. A non-gravid female (87.0 cm SVL, 574 g mass) crossed a milo field and took refuge in a woodpile in a roadside ditch as she traveled between two woodland patches. She traveled across this field again on 21 September 1999 as she returned to her previous location. In this case a woodland corridor was not available.

The remaining three snakes were not found traveling through agricultural fields but had instead taken refuge in them on various occasions. On 8 August 1999 a small female *C. horridus* (68.2 cm SVL, 250 g mass) was radiotracked to a cornfield adjacent to the wooded area she had previously been occupying. She remained in the cornfield for 13 days during which time she shed her skin and successfully fed. On 14 September 1999, an adult male *C. horridus* (88.7 cm SVL, 547 g mass) was found in a soybean field exhibiting a classic ambush posture. He remained in the soybean field for 14 days but did not successfully feed and was subsequently found foraging in a woodland strip adjacent to the soybean field on the 15th day. Neither of these individuals used row crop fields on more than one occasion. However, a female (73.0 cm SVL, 320 g mass) used a soybean field on two separate occasions for a total of 34 days, which constituted 31.5% of her total summer activity time. She initially entered the soybean field on 19 July 1999 and remained there for 20 days, at which time she entered a strip of tall grass and shrubs separating the soybean field from a small creek. She shed and fed while in this grassy area and re-entered the soybean field to digest her food on 6 September 1999, remaining there for 14 days until she began migrating back to her den. This snake did not appear to be foraging in the soybean field and in fact left the beans to feed in the buffer strip. We suspect that the microclimate beneath the soybean canopy was favorable, which may explain an apparent preference by this snake for such an unusual habitat.

The high incidence of agricultural field use by *C. horridus* in Nebraska may be explained by their biogeography. This population of *C. horridus* is at the extreme periphery of their range, thus preferred habitat is scarce and available habitat is sub-optimal. These kinds of pressures often create situations where such aberrant behaviors are more prevalent than they are in the center of a range.

We thank the University of Nebraska at Omaha (UNO) Committee on Research, the UNO Department of Biology, The

Chicago Herpetological Society, and the Nebraska Herpetological Society for financial assistance with this study.

Submitted by **DANIEL D. FOGELL**, Department of Biology, University of Nebraska at Omaha, Omaha, Nebraska 68182-0040, USA (e-mail: dfogell@unomaha.edu), **TED J. CROTALUS HORRIDUS HORRIDUS (Timber Rattlesnake). **CLIMBING**. During a radiotelemetry study in Gage County, Nebraska, USA, climbing behavior by *Crotalus h. horridus* was observed on four separate occasions. On 18 May 1999, a subadult female *C. h. horridus* (68.2 cm SVL, 250 g mass) was radiotracked to a riverbank where she was located ca.1.5 m high in a recently felled tree. The snake was wedged between the outer bark and the inner wood. She remained in this position for two days. Her previous location was < 1 m above the water line of the Big Blue River, thus it is possible that rising water levels in the river because of recent heavy precipitation may have forced an upward retreat.

On 19 May 1999, an adult male timber rattlesnake (89.0 cm SVL, 545 g mass) was found coiled and basking on a primary branch of an ash tree (*Fraxinus* sp.) at a height of ca. 3 m. This snake was captured for inclusion in the radiotelemetry study and was released on 22 May 1999 on the same branch. After being released, the snake retreated into a hole in the branch and remained there for one day. The tree was located in a clearing on the upper slope of riparian woodland and was commonly used as a basking site for adult black rat snakes (*Elaphe obsoleta obsoleta*).

Another radiotracked female (73.0 cm SVL, 320 g mass) was observed on 12 June 1999 leaving the lower branches of a small cottonwood tree (*Populus deltoides*) ca. 2 m above the ground. Her shed skin was found interwoven among the branches. The site was located on the bank of a dry stream. Apparently, this snake was using the tree branches to assist in sloughing off her skin.

A gravid female (84.8 cm SVL, 700 g mass) was radiotracked on 7 July 1999 at 0900 h to a large pile of discarded corrugated metal at the base of a red mulberry tree (*Morus rubra*). A dead branch was lying across the metal pile at a height of 2 m above the ground and 1 m above the metal. The gravid female timber rattlesnake was stretched along the dead branch in such a position that her abdominal region was draped over the branch and above the metal so that the developing follicles were receiving reflective heat from the warm metal surface. The air temperature on the branch above the metal was 30.5°C whereas the temperature 2 m away from the metal was 27.4°C.

Although climbing behavior has been previously reported in *C. horridus* (Saenz et al. 1996. Herpetol. Rev. 27:145), it is uncommon and is often explained as either foraging behavior or an attempt to escape rising flood waters. Of the four accounts described above, only one (19 May 1999) could possibly be described as foraging behavior, however none of the telemetered snakes in this study fed before 20 June 1999. The 18 May 1999 account is probably explained by rising water. The remaining two, however, clearly were neither foraging nor escaping rising water. Additionally, there have been no other reports of gravid timber rattlesnakes exhibiting climbing behavior.

We thank the University of Nebraska at Omaha (UNO) Committee on Research, the UNO Department of Biology, The Chicago Herpetological Society, and the Nebraska Herpetological Society for financial assistance with this study.

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake). **MALE COMBAT.** A proximate goal of male combat in *Elaphe obsoleta obsoleta* is to achieve physical superiority over an opponent and establish dominance (Gillingham 1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 184–209. McGraw-Hill Publishing Co., New York). Presumably, the ultimate goal of such combat is to provide the victor with priority access to an estrous female. However, the functional significance of combat in the reproductive biology of the species has not been clearly demonstrated.

There are few published observations of male combat in free-ranging black rat snakes. Stickel et al. (1980. Amer. Midl. Nat. 103:1–14) recorded three instances of combat in a 35-year Maryland study and one observation each was reported by Rigley (1971. J. Herpetol. 5:65–66) and Mitchell (1981. Catesbeiana 1:7–9). All of these observations have taken place during the spring to early summer breeding season; however, the presence of a female was noted in only one report (Mitchell, *op. cit.*) with no male-female interactions recorded.

Whatever role combat may play in reproduction, these records suggest that the physical presence of a female is not essential to initiate male combat. It is possible that females have been present but hidden during observations of combat in free-ranging males; however, in laboratory trials of male combat conducted with captive male black rat snakes, initiation of combat sequences did not involve females (Gillingham 1980. Herpetologica 36:120–127).

On 9 June 1996, we observed male combat in a pair of free-ranging *E. o. obsoleta* and did not find any females present. We were able to recognize behaviors analogous to those defined by Gillingham (*op. cit.*) from combat sequences with captives. These observations occurred in Hanging Rock State Park in Stokes County, North Carolina, USA, and are summarized below.

The snakes were initially discovered 2.5 m from a residence and adjacent to an area where one or more unidentified *E. o. obsoleta* had been observed regularly over several days. When first observed at 1305 h, the snakes were fully entwined along their body lengths except for their anterior 20–25 cm. This intertwining was maintained during the entire combat episode, although it was not a static position. At times the smaller snake appeared to be held in a "corkscrew" of the larger snake's coils (Fig. 1). The snakes would occasionally entwine almost to their heads. The larger of the two snakes (122 cm) appeared to be attempting to press down upon the smaller (107 cm) snake's head. During periods of these head pressing jousts, both snakes formed short, lateral, and U-shaped curves of the neck immediately posterior to the head (Fig. 2) and used these to press downwards

FIG. 1. Smaller snake held in "corkscrew" of dominant male's coils during combat between male *Elaphe obsoleta* in Stokes County, North Carolina, USA.

FIG. 2. Head pressing posture in the form of lateral, U-shaped curves of the neck during combat between male *Elaphe obsoleta* in Stokes County, North Carolina, USA.

on the opponent. Intermittently, the larger snake would poise this body arrangement over the head of the smaller snake (Fig. 2) and would then attempt additional downward presses. When both snakes formed this U-shaped posture in opposite directions they would seem to face each other, forming a "caduceus." At times, both snakes' fore bodies would lift off the ground to nearly vertical, and then the larger snake would press down upon the area immediately posterior to or directly on the head of the smaller snake bringing him back horizontal to the ground. At no time during active engagement did the snakes seem concerned about human observers ≤ 2 m away.

At 1350 h the smaller snake broke away and was pursued by the larger snake into shrubbery adjacent to the house. The smaller snake fled the shrubbery, moving back into the open yard, and was no longer pursued by the larger snake. Remaining in the shrubbery, the larger snake appeared to be moving towards an opening in the house's siding 2 m away. With the combat apparently terminated, both snakes were captured for sexing and measurement and were then immediately released at their points of capture. After release the smaller snake left the area and the larger snake fled 15 m from the release site and entered root tunnels beneath dense vegetation. At 1530 h the larger snake (identified by old scars along his dorsum) had returned to the point of combat. Due to rapid tongue flicking and a sweeping motion of the head he appeared to be searching. No other snakes were found.

Black rat snakes are mobile, exhibit overlapping home ranges (Fitch 1963. Copeia 1963:649–658), and frequent certain large, isolated trees that serve as focal points common to the range of many individuals in the population. These focal trees are visited repeatedly by both sexes and are used for basking, shedding, courtship, and mating (Stickel et al., *op. cit.*; J. Flora, pers. comm.). Perhaps the stimulus to establish male intrasexual dominance in the absence of females is based on the expectation of future encounters in the presence of estrous females.

We thank M. E. Dorcas, W. H. Martin, J. C. Mitchell, and M. P. Rowe for comments on the manuscript.

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake). **PREDATION.** Birds are among the many vertebrate predators of snakes. In particular, raptors and herons have frequently been observed preying on snakes (Fitch 1963. Copeia 1963:649–658; Godley 1980. Ecol. Monogr. 50:411–436; Toland 1985. J. Field Ornithol. 56:419–422; Jennings 1997. Herpetol. Rev. 28:205–206; Vandermast 1999. Herpetol. Rev. 30:169). Predation on snakes by birds other than raptors or herons is less common and these species generally prefer small individuals. American robins (*Turdus migratorius*), loggerhead shrikes (*Lanius ludovicianus*), and bluejays (*Cyanocitta cristata*) are some of the species that prey on small snakes (Plummer 1990. J. Herpetol. 24:327–328; Mahrdt and Banta 1996. Herpetol. Rev. 27:81; Hedeen 1998. Herpetol. Rev. 29:103). Herein, we report a predation attempt by an American crow (*Corvus brachyrhynchos*) on an adult of a large species, the black rat snake, *Elaphe obsoleta obsoleta*.

On 31 May 2000 at ca. 1600 h we observed a live adult *E. o. obsoleta* (920 mm SVL, 980 mm TL) on the pavement on the south side of Little River Road, Great Smoky Mountains National Park, Tennessee, USA ca. 0.5 mi E of Metcalf Bottoms Campground (Wear Cove Quadrangle, 35°40'19"N, 83°38'23"W, ca. 561 m elevation). An adult *C. brachyrhynchos* was pecking the snake. The snake had ca. 10 wounds on its head and body, with the greatest number of wounds (4) concentrated cranially. The right eye had been enucleated, the right mandible and the crown of the skull lacerated, and the snake could not tongue-flick and had great difficulty moving and orienting. After we collected and euthanized the snake, it was palpated and no additional injuries (spinal fractures or other major traumas) were observed, ruling out the possibility that the snake was first hit by a car and then attacked by the crow. All wounds appeared to be consistent with injuries sustained during the observed predation attempt.

American crows are predators of small snakes and will mob potential predators, including snakes (Kale and Maehr 1990. Florida's Birds. Pineapple Press, Sarasota, Florida. 288 pp.). The event described here does not appear to have begun as a mobbing

incident, however, as no other crows were present at the time of the observations and Fitch (*op. cit.*) observed that actual attacks on *E. o. obsoleta* during mobbing are very unusual. Predatory attacks by passerine birds on adults of large snake species are also unusual, and this is the first documentation of a predatory attack by *C. brachyrhynchos* on an adult *E. o. obsoleta*.

These observations were made in conjunction with the USGS Southeastern Amphibian Research and Monitoring Initiative under permits from Great Smoky Mountains National Park (GRSM 00-025) and the Tennessee Wildlife Resources Agency (No. 1103). The specimen will be deposited in the National Museum of Natural History. We thank Lora L. Smith and C. Kenneth Dodd, Jr. for comments on the manuscript.

ERYX JAYAKARI (Arabian Sand Boa). **REPRODUCTION**. No published accounts of reproduction for *Eryx jayakari* could be found, yet this species is generally assumed to be viviparous as has been recorded for several other *Eryx* species. We report here the first recorded successful captive breeding, egg laying, and hatching for this species. Both oviparity and viviparity are represented in other genera of snakes (e.g., *Elaphe*, *Vipera, Natrix, Trimeresurus*) (Tinkle 1977. Misc. Pub. Mus. Zool. Univ. Michigan, No. 154), however, this is the first record for both reproductive modes within the genus *Eryx*.

One female (64 g) and two male (23 and 51 g) *Eryx jayakari* (imported from Saudi Arabia in 1999) were introduced after a mild brumation. The female later showed obvious signs of pregnancy and laid one infertile and six fertile eggs on 12 August 2001. The eggs were incubated in slightly moistened vermiculite at 31–33°C. The hatchlings pipped the eggs on 17 October 2001 after incubating for 66 days. Just prior to hatching (01 October), egg masses were 9.9, 10.2, 10.6, 11.5, and 12.7 g. The masses of the hatchlings were 4.5, 4.8, 4.9, 5.3, and 5.5 g. The sixth fertile egg began to decompose part way through the incubation, and contained a partially developed embryo.

FIG. 1. Two *Eryx jayakari* emerging from eggs. The tight fit of the egg shell around the hatchling's neck upon emergence is especially visible in the animal on the left.

The hatchlings did not appear to possess an egg tooth. Instead they ruptured the thin shell of the egg with their head by force. This action created rough tears in the shell rather than smooth cuts as has been observed for other species including *Calabaria reinhardtii* (pers. obs.).

We have recently become aware of a second instance of oviparity in sand boas. A captive female *Eryx muelleri* laid four thin-shelled eggs and a single hatchling emerged after a very short incubation period (14 days). The hatchling, as in *E. jayakari*, also lacked an egg tooth (Bruce Miller, pers. comm.).

Submitted by **RICHARD E. STAUB**, Department of Nutritional Sciences and Toxicology, University of California, Berkeley, California 94720, USA (e-mail: rstaub@nature.berkeley.edu), and **JOHN EMBERTON,** East Bay Vivarium, 1827 Fifth Street, Berkeley, California 94720, USA.

LAMPROPELTIS PYROMELANA (Sonoran Mountain Kingsnake). **DIET.** Here I provide the first evidence for chiropterophagy by the genus *Lampropeltis* (see Schätti 1984. Bonn. Zool. Beitr. 35:335–342, for a review of chiropterophagy by snakes). An adult female *L. pyromelana* (705 mm SVL) was collected DOR on Hwy 80, 37 km S of Interstate 10, Hidalgo Co., New Mexico, USA by Sandilee Burgess, August 1996. A long-legged myotis bat (*Myotis volans*) was found partially digested in the stomach of the snake. The snake and bat were deposited into the collections of the University of Michigan Museum of Zoology (UMMZ 225039, 172544 respectively).

Subitted by **GLENN M. FOX**, Department of Ecology and Evolutionary Biology and Division of Reptiles and Amphibians, University of Michigan Museum of Zoology, Ann Arbor, Michigan 48109-1079, USA; e-mail: foxg@umich.edu.

MASTICOPHIS FLAGELLUM (Coachwhip). **OPHIOPHAGY**. *Masticophis flagellum* is known to take a variety of prey items including snakes: *Arizona elegans* (Small et al. 1994. Herpetol. Rev. 25:28); *Diadophis punctatus* and *Heterodon platirhinos* (Hamilton and Pollack 1956. Ecology 37:519–526); *Opheodrys aestivus* (Reams et al. 2000. Herpetol. Rev. 31:247); *Thamnophis butleri* and *T. sirtalis* (in captivity); *Crotalus atrox* (Ortenburger 1928. Mem. Univ. Michigan Mus.1:1–247); and *Crotalus viridis* (Tabor and Germano 1997. Herpetol. Rev. 28:90). Smith (1956. Misc. Publ. Univ. Kansas Mus. Nat. Hist. 9:1–357) also described *M. flagellum* as preying on other snakes. Here we report a snake as a prey item not previously documented for *M. flagellum*.

On 4 May 1980 a *M. flagellum* was observed ingesting a live gopher snake (*Pituophis catenifer*) between Black Canyon Petroglyphs and Harper Dry Lake (north of Barstow), San Bernardino County, California, USA. The *M. flagellum* had hold of the *P. catenifer* by the tail and was proceeding to swallow it. The two snakes struggled for almost one hour before the *M. flagellum* had completely ingested the *P. catenifer*. The snakes were photographed and a color slide was deposited in the Natural History Museum of Los Angeles County (LACM PC 1339).

MICRURUS CORALINUS (Coral Snake). **ENDOPARASITES.** Travassos (1917. Mem. Inst. Osw. Cruz 9:5–62) first reported *Oligacanthorhynchus spira* cystacanths in snakes. Travassos (*op. cit.*) found larvae attached to the peritoneum of many snakes including *Boa, Clelia, Erythrolamprus, Liophis, Lystrophis, Mastigodryas, Philodryas, Waglerophis, Bothrops,* and a snake possibly misidentified as *Dipsadomorphus dendrophilus.* Adults were also found in the intestines of birds including *Cathartes, Coragyps, Sarcoramphus,* and *Buteogallus*. This note reports the first occurrence of cystacanths of *O. spira* in *Micrurus corallinus* (Elapidae).

Snakes (N = 89) were collected in São Paulo state, southeastern Brazil, fixed in 10% formalin and preserved in the collection of Instituto Butantan (São Paulo, SP). They were dissected, and the cystacanths were extracted and dehydrated in ethyl alcohol and gradient cleared in methyl salicylate, a procedure modified from Torres and Puga (1996. Mem. Inst. Osw. Cruz 91:717–719). All larvae of *O. spira* were found in the peritoneum of the snakes. The prevalence of cystacanths was 28.08% and the mean intensity of infection was 24.92 larvae/snake (±1.01 SD), ranging from 1 to 144 larvae/snake.

Micrurus corallinus feed mainly on amphisbaenians, a few elongate lizards, caecilians, and other snakes (Marques and Sazima 1997. Herpetol. Nat. Hist. 5:88–93), whereas cystacanths often occur in invertebrates (Schmidt and Roberts 1996. Foundations of Parasitology. 5th ed.W. C. Brown Publ., Dubuque. 659 pp.). We suspect that *M. corallinus* become infected with cystacanths by consuming insectivorous prey.

We thank Otavio Marques and Francisco Luís Franco for help in current snake taxonomy and permission to examine specimens. We also thank Marlene T. Ueta for general suggestions. Finally, we thank André Victor Lucci de Freitas, Arício X. Linhares, Ivan Sazima, and José Roberto Trigo for critically reviewing this note.

MADI,** Depto. de Parasitologia, Instituto de Biologia, Universidade Estadual de Campinas, CP 6109, 13083-970, Campinas, São Paulo, Brazil (e-mail: rmadi@unicamp.br).

MICRURUS FRONTALIS PYRRHOCRYPTUS (Coral Snake)**. PREDATION**. Observations of predation on *Micrurus* by birds are scarce (Pough 1988. *In* Gans and Huey [eds.], Biology of the Reptilia Vol. 16, pp. 153–234. Alan R. Liss, Inc., New York; Roze 1996. Coral Snakes of the Americas: Biology, Identification and Venoms. Krieger Publ., Malabar, Florida. 328 pp). Here I report predation by *Cariama cristata* (red-legged chuña or seriema, Aves: Cariamidae) on *Micrurus f. pyrrhocryptus*. The event occurred on 10 April 2000 at 1500 h in the Graciela Ranch (29°40.945'S, 64°02.443'W), Departamento Sobremonte in the northwest of the Province of Cordoba, Argentina. The adult snake (ca. total length 30 cm) was first seen by the semi-tame, but wild, bird from a distance of ca. 6 m. The bird ran rapidly toward the snake and captured it by the head. I followed and observed the encounter from a distance of a meter or less. First, the bird crushed the head with repeated closures of its beak, then still holding it by the head, it lifted the coral snake into the air and rapidly swung it downwards onto the ground. The action was similar to that used by roadrunners ("centrifugal-slam" technique; Sherbrooke 1990. Wilson Bull. 102:171–174). Possibly this was to ensure that the snake was dead. Then it dropped the snake onto the ground and waited 15–30 sec. before picking it up again in its beak, near the head. The bird then proceeded to reposition its thin-bodied prey in its beak several times before beginning to ingest it, a section posterior to the head entering first and leaving two portions extending from its mouth. Ingestion (encompassing at least 2 min.) proceeded until first the head end was completely engulfed and then the tail end. Snakes are uncommon prey items of *Cariama cristata* (Sick 1993. Birds in Brazil: A Natural History, pp. 217–219. Princeton University Press, New Jersey). This observation suggests that the red-legged chuña or seriema does not have an innate fear response to coral-snake colors and pattern, as has been reported in other birds (Smith 1975. Science 187:757–760; Smith 1977. Nature 265:535–536), and that coral snakes, despite being venomous, may not have an effective defense against the bird's attack.

I thank Wade C. Sherbrooke, Mike Westphal, and M. Gabriela Perotti for assistance.

Submitted by **MARIANA PUETA**, Cátedra de Diversidad Animal II, F.C.E.F y N, Universidad Nacional de Córdoba, Av. Velez Sarsfield 299, CP 5000, Córdoba, Argentina; e-mail: maripueta@hotmail.com.

RHADINAEA FORBESI (Forbes's Graceful Brown Snake). **REPRODUCTION**. Reproductive data for this species are unknown owing to its rarity in collections—a consequence of fossorial habits and geographic restriction to the high mountainous region of central Veracruz, Mexico (Myers 1974. Bull. Amer. Mus. Nat. Hist. 153:1–262). Miguel Angel de la Torre Loranca collected a gravid female at Petlacala, Municipio de San Andres Tenejapan, Veracruz, Mexico (18°47'N, 97°06'W, 2100 m elev.) on 11 March 2000 in a pine-oak forest (see Lopez-Luna et al. 1999. Herpetologica 55:382–389, for a complete description of the habitat and location). The snake deposited four eggs measuring 10 mm x 23.2 mm and weighing 1.4 g (mean) on 12 April 2000. The female weighed 17.6 g on 11 April the day before oviposition, and 12.1 g on 12 April after oviposition. The eggs were incubated in a 1:1 ratio by weight of vermiculite and water at a constant temperature of 28°C. Four hatchlings emerged after 51 days of incubation. Hatchlings measured 15.97 cm total length and weighed 1.69 g (mean). The female and hatchlings were deposited in the herpetological collection of Estación de Biología Tropical Los Tuxtlas. This is the first known register of reproduction for this species.

STORERIA DEKAYI DEKAYI (Northern Brownsnake) and ***S. OCCIPITOMACULATA OCCIPITOMACULATA*** (Northern Red-bellied Snake). **MORPHOLOGY**. Apical pits are reportedly absent in snakes of the genus *Storeria* (Boulenger 1893–1896. Catalogue of Snakes in the British Museum (Natural History). 2nd ed. 3 vols. Taylor and Francis, London. 727 pp.; Trapido 1944. Amer. Midl. Nat. 31:1–84.; Wright and Wright 1957. Handbook of Snakes of the United States and Canada. 2 vols. Comstock Publ. Co., Ithaca, New York. 640 pp.; Marx and Rabb 1972. Fieldiana Zool. 63:92–99). Herein, I report on the discovery of apical pits in two species of *Storeria*.

As part of an ongoing project dealing with the identification of shed skins, I examined 145 sheds of 21 species of North American snakes. Of the 145 sheds, six *S. d. dekayi* and eight *S. o. occipitomaculata* sheds were included for study. After being cut into sections and mounted, sheds were examined using a stereo microscope under 10x and 30x magnification. Data for various characters, including the presence or absence of apical pits were recorded. Two *S. d. dekayi* and four *S. o. occipitomaculata* sheds had apical pits on scales on the dorsal neck region (Fig.1), whereas scales beyond the nape had no observable pits.

Several factors may have been responsible for apical pits being overlooked in *Storeria* for so long. First, apical pits may be restricted and or more apparent on certain areas of the body (e.g., some specimens of *Lampropeltis triangulum*; Williams 1978. Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. Publ. Biol. Geol. Milw. Publ. Museum 2:1–258). Second, apical pits are best seen in shed skins (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. SSAR, Oxford, Ohio. 614 pp.). Also, it is evident that significant interspecific and intraspecific variation occurs in some groups (Ball 1996. Reptile & Amphibian Magazine. July/Aug 1996:112–116); less than half (43%) of the *Storeria* sheds in the present study had observable apical pits. The techniques used to prepare (e.g., mounting) and examine (e.g., intensity and angle of lighting) shed skins or actual specimens may affect how easily these structures are observed. If a structure is reported as absent, some may choose not to look for them. Intraspecific variation in the occurrence of apical pits warrants additional study.

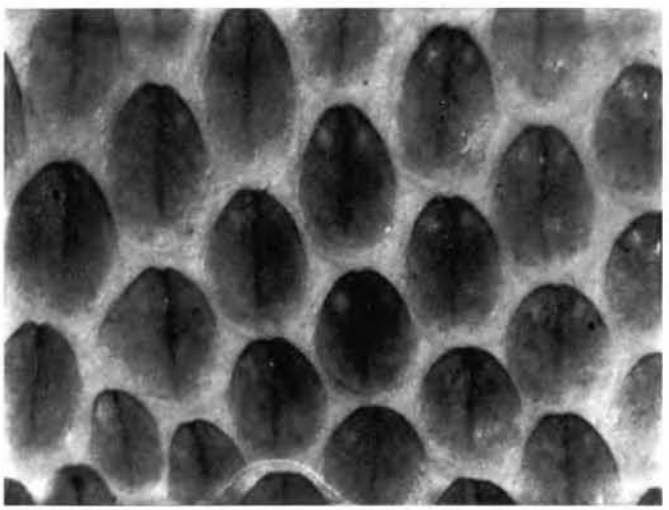

FIG. 1. Dorsal scales with apical pits on a shed skin of *Storeria dekayi dekayi* from Erie Co., Pennsylvania, USA.

I thank Brian Wettekin and Paul Curtis for providing field collected sheds, Hobart Smith for help with the literature and reviewing an earlier version of the manuscript, James Ball for confirming the presence of apical pits on the *Storeria* sheds, providing the microphotograph, and for reviewing a draft of the manuscript. I also thank James Harding whose suggestions were helpful in the final preparation of the manuscript.

Submitted by **BRIAN S. GRAY**, 1217 Clifton Drive, Erie, Pennsylvania 16505, USA.

XENOPELTIS UNICOLOR (Asian Sunbeam Snake). **DIET.** Tooth morphology of *Xenopeltis unicolor* is specialized for handling lizard prey (e.g., skinks; Greene 1997. Snakes: The Evolution of Mystery in Nature. Univ. California Press, Berkeley. 351 pp.). We report the first occurrence of oophagy by *X. unicolor*. An adult male *X. unicolor* (774 mm SVL) had two unidentified squamate eggs, measuring 23 and 29 mm in length, in its stomach. Each egg had been slit along the side one or more times and was empty. The snake was collected by Kamuran Tepedelen in central Java, Indonesia in June 1999. Both the *X. unicolor* and its stomach contents are part of the herpetological collections at the University of Michigan Museum of Zoology (UMMZ 227200 and UMMZ 227201, respectively).

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2002 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Theodora Pinou, SSAR Treasurer, Department of Ecology & Evolutionary Biology, Osborn Memorial Labs, Yale University, 165 Prospect Street, New Haven, Connecticut 06520-8106, USA. Fax: (203) 432-5176; e-mail: theodora.pinou@yale.edu

Future Annual Meetings

2003 — Hotel Tropical, Manaus, Brazil, 26 June–2 July (with ASIH, HL)
2004 — University of Oklahoma, Norman, Oklahoma (with ASIH, HL)
2005 — University of South Florida, Tampa, Florida (with ASIH, HL)

About Our Cover: *Hemiphractus helioi*

A half-dozen hylid frog species comprise one of the most distinctive, if not the weirdest, groups in the family (Mendelson et al. 2000. Zool. J. Linnean Soc. 128:1–24). Called casque-heads owing to their large, box-like skulls, frogs in the genus *Hemiphractus* look like props from a Star Wars movie set. Bony processes ornament the head and fleshy protuberances adorn the eyelids and snout, and the over-sized mouth contains sharp, fang-like maxillary and premaxillary teeth. Bulging eyes with horizontal pupils give these hylids a decidedly extraterrestrial appearance.

Casque-heads are known only from lower Central America, and South America in the Chocó, the Andes Mountains, and the western Amazon Basin. The genus is considered to show an Amazonian distribution (*Hemiphractus bubalus*, *H. helioi*, *H. proboscideus*, and *H. scutatus*), with *Hemiphractus fasciatus* and *H. johnsoni* being Chocoan vicariants (Duellman 1999. *In* W. E. Duellman [ed.], Patterns of Distribution of Amphibians, pp. 255–328. Johns Hopkins University Press, Baltimore; Trueb 1974. Occasional Papers of the Museum of Natural History, University of Kansas 29:1–60). *Hemiphractus* is known to occur in Panama, Colombia, Ecuador, Peru, and Bolivia.

These frogs live in dense, tropical rainforest and cloud forest up to about 2000 m above sea-level. They look for all the world like the leaf litter in which they hide during daytime. By night casque-heads can be found perched on low twigs and leaves or sitting in ambush (*H. scutatus*) on the forest floor. The diet consists of arthropods and small vertebrates, especially frogs. Prey is seized rapidly and subdued by a powerful bite. Vocalization is only spottily documented, and calling behavior is unknown for several species. The breeding biology of casque-heads also is an enigma, although females of some species have been found brooding eggs on their backs.

After a hiatus of nearly three decades (Trueb 1974, *op cit.*), relationships among hemiphractines recently have been the subject of much investigation (Mendelson et al. 2000, *op cit.*; Sheil and Mendelson 2001. Herpetologica 57:189–202; Sheil et al. 2001. Herpetologica 57:203–214). The discovery of a previously undescribed species, *Hemiphractus helioi*, that had been ascribed erroneously to *H. johnsoni* for nearly a century, has altered our concept of *Hemiphractus*. Two lineages are recognized currently, with *H. johnsoni* being the sister taxon to *H. bubalus* + *H. proboscideus*, and *H. helioi* being the sister taxon to *H. fasciatus* + *H. scutatus* (Sheil et al. 2001, *op cit.*).

The cover photograph depicts a *Hemiphractus helioi* (Helio's Casque-head) feeding on an *Eleutherodactylus carvalhoi*, which it ingested over a period of several minutes. The photo was taken by **William W. Lamar**, who found and photographed the frogs *in situ* at night in leaf litter of low primary rainforest near a swamp in eastern Peru, adjacent to the Brazilian frontier. Lamar used a Pentax LX camera, Vivitar Series 1 f/2.5 90mm macro lens, extension tubes, Vivitar Series 1 flash, and Fuji Velvia film.

PHOTO BY PEKKA SONNI

Lamar comments that he has observed *H. helioi* in adjacent western Brazil, and that the species is widespread across northeastern Peru in the Departamento de Loreto, where he has found it in sympatry with *H. proboscideus* and *H. scutatus*, always in primary rainforest, and always at night.

Bill has spent half of his life in the Neotropics, and much of that time he has been carefully documenting the remarkably diverse herpetofauna of the western Amazon Basin in Colombia, Ecuador, and Peru for a book he is writing. Lamar believes the best way to become environmentally aware is by celebrating nature, and towards that end he leads specialists as well as the general public on tropical expeditions for GreenTracks, Inc. Jonathan A. Campbell of the University of Texas at Arlington and Bill have just completed a new book, "**The Venomous Reptiles of the Western Hemisphere**," to be published next year by Cornell University Press.

SSAR BUSINESS

North American Common Names Publication Now Available Online

As a service to the herpetological community, SSAR has made the official list of names of amphibians and reptiles of North America free for download as a PDF file (ca. 1.6 MB). "*Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*" by the Committee on Standard English and Scientific Names (Brian I. Crother, Chair) is now available at:

http://www.herplit.com/SSAR/circulars/HC29/Crother.html

A printed version of the book may be ordered from the SSAR Publications Secretary at:

http://www.herplit.com/SSAR/index.html

This names list has been adopted by all three North American herpetological societies (ASIH, HL, SSAR) as the official list of accepted common names, and also serves as an important resource for current taxonomic arrangements for North American taxa.

SSAR Grants-in-Herpetology Committee Annual Report (2002)

An award in the amount of US $500 was made to each of the following individuals:

Field Research.—**Jerry Husak**, Oklahoma State University. Project title: "Environmental constraints on the evolution of collared lizard (genus *Crotaphytus*) display behavior and coloration."

International.—**Christopher Kelly**, Oxford University. Project title: "Afromontane snakes: species boundaries, phylogenetics and phylogeography."

Conservation.—**Michael J. Rubbo**, Pennsylvania State University. Project title: "Urbanization, ecosystems, and amphibians: Do changes in ecosystem functioning prescribe the composition of amphibian communities?

Laboratory Research.—**Carol L. Spencer**, University of Texas at Arlington. Project title: "Phylogeography and comparative analysis of a widespread pitviper, *Crotalus atrox*.

Travel.—**Julie E. González**, Iowa State University. Project title: "Inheritance of nest-site choice in the field in a turtle with temperature-dependent sex determination."

2002 Grants-in-Herpetology Committee.—Chair: Erik R. Wild. Reviewers: Jeffrey Parmelee, Karen Lips, Kirsten Nicholson, Rafael de Sá, and Chris Parkinson.

SSAR congratulates the 2002 GIH recipients and thanks the committee members for their efforts.

Seibert Award Winners for 2002 Announced

The eleventh annual Seibert Awards were presented at the 45th Annual Meeting of the SSAR in Kansas City, 3–8 July 2002. These

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
2003 ANNUAL MEETING

together with

THE HERPETOLOGISTS' LEAGUE

and

AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS

26 June – 1 July 2003
Tropical Hotel Conference Center
(on the Rio Negro)
Manaus, Amazonas, Brazil

Richard C. Vogt and Ning Labbish Chao, Local Chairs

First Announcement

A more detailed meeting announcement will appear in the December 2002 issue of *HR*.

The Meeting Announcement/Call for Papers will be mailed to all members of the sponsoring societies 1 November 2002. It is also available as a PDF file at <http:www.fua.br/jmih2003.html>.

Travel: Varig Travel Vacations is offering a package airfare and hotel round trip from Miami to Manaus with 6 nights in Hotel Tropical with breakfast and buffet lunch US$ 1300 per person double occupancy. Add on prices from other cities can be arranged. <www.varigtravelvacations.ws> or 1-877-687-1000. Attendees may also download the Varig Travel Package reservation form (PDF file) from the SSAR web site: <http://www.ku.edu/~ssar/Manaus_Regform.pdf>

awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meeting, a single award was given in each of the following categories: Systematics (4 eligible presentations), Physiology/Morphology (8 eligible presentations), Ecology/Evolution (19 eligible presentations), and Conservation (10 eligible presentations). All four awardees received a check for US $200 and a book from Academic Press. The winners:

Systematics: **Gregory Pauly**, Section of Integrative Biology, University of Texas at Austin, "Phylogenetic Relationships of North American Bufonids."

Physiology/Morphology: **Gabriel Rivera**, Department of Biological Sciences, Old Dominion University, "Regional Variation in Mechanical Properties of the Integument of *Thamnophis sirtalis* (Serpentes)."

Ecology/Evolution: **Jason Kolbe**, Department of Biology, Washington University, "A Comparative Study of Interspecific Interactions among Three Antiguan Lizards."

Conservation: **John Roe**, Department of Biology, Indiana-Purdue University, "Wetland Use Patterns and Spatial Ecology in Two Sympatric Water Snakes, *Nerodia sipedon* and the imperiled *Nerodia erythogaster neglecta*."

The judges also acknowledged additional outstanding presentations as Honorable Mention recipients:

Systematics: **Ted Townsend**, Department of Biology, Washington University, "Phylogeography and Species Status of Dwarf Chameleons of the *Bradypodion transvaalense* Complex of South Africa."

Physiology/Morphology: **Charles Smith**, Department of Ecology and Evolutionary Biology, University of Connecticut, "Sexual Dimorphism in the Forked Tongue of the Northern Copperhead Snake."

Ecology/Evolution: **Erin Casey**, Department of Biological Sciences, Eastern Illinois University, "Genetic Diversity, Phylogeography, and Conservation of the Seal Salamander, *Desmognathus monticola*." **Patrick Owen**, Department of Ecology and Evolutionary Biology, University of Connecticut, "Graded Aggressive Response in the Green Frog *Rana clamitans*." **Jessica Stapley**, School of Botany and Zoology, Australian National University, "The Behavioral Responses of Lizards to Multiple Predators."

Conservation: **Tracy Green**, Division of Biological Sciences, University of Missouri, "Salamanders Alter Emigration Behavior at a

Forest-Grassland Edge: Variation among Metamorphs, Adults, and Translocated Adults." **Deni Porej**, Department of Evolutionary, Ecology and Organismal Biology, The Ohio State University, "Amphibian Aspect of Mitigation for Wetland Losses."

The judges were Robin Andrews (Virginia Polytechnic and State University), Chris Austin (University of North Dakota), David Bickford (University of Miami), Steve Johnson (U.S. Geological Survey), Peter Nelson (Emory University), Kirsten Nicholson (Washington University), Chuck Peterson (Oklahoma State University), Marion Preest (Chair, The Claremont Colleges), and Lora Smith (Joseph W. Jones Ecological Research Center).

Proposed Amendment to SSAR Bylaws

Members of the Society for the Study of Amphibians and Reptiles are hereby notified of a proposal approved by the SSAR Board of Directors to amend the following articles of the SSAR Bylaws to alter the terms of office for several officers to either two- or four-year terms (dependent upon position) and increase the number of Directors from six to eight. The purpose of the amendments is to increase the number of board members and enable the SSAR to benefit more fully from their expertise and acquired knowledge of the society. These changes will furthermore allow elections for officers be held only every other year, rather than annually, as also approved by the Board.

Article II, Section 1a, currently reads: "The elected officers shall be President, President-elect, Secretary, Treasurer, six Directors and the immediate past President."

If amended, it will read: "The elected officers shall be President, President-elect, Secretary, Treasurer, eight Directors and immediate Past-President."

Article II, Section 3, currently reads: "The terms of office for the President, President-elect and immediate Past-President shall be for two years; those for Secretary, Treasurer, Publications Secretary and Directors shall be for three years (with election to provide staggered terms so that no more than two Directors shall be elected in any one year)."

If amended, it will read: "The terms of office for the President, President-elect, Secretary, Treasurer, Publications Secretary, and immediate Past-President shall be for two years; those for Directors shall be for four years (with election to provide staggered terms so that no more than four Directors shall be elected in any one year)."

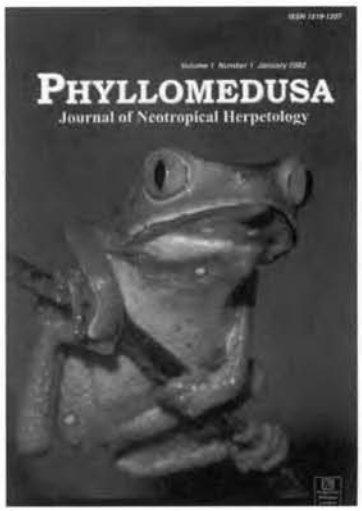
Article III, Section 1, currently reads: "The Board of Directors shall consist of the President, President-elect, Secretary, Treasurer, six Directors, Publications Secretary and immediate Past-President.

If amended, it will read: "The Board of Directors shall consist of the President, President-elect, Secretary, Treasurer, eight Directors, Publications Secretary and immediate Past-President."

These proposed amendments will be on the agenda for discussion at the 2003 annual business meeting in Manaus, Brazil (precise date and time to be determined). A ballot on the amendments will be submitted to the SSAR membership after the annual meeting in Manaus. The new terms of office would take effect in 2005 for those persons elected by mail ballot in 2004.

NEWSNOTES

International Society for the History and Bibliography of Herpetology



The ISHBH is a not-for-profit organization established to bring together individuals for whom the history and bibliography of herpetology is appealing and to promote the knowledge of related topics among members and the general public. Membership is open to anyone who shares the aims of the society. Members receive the biannual ISHBH Newsletter and Bulletin. The society also organizes seminars, visits to libraries, museums, research stations, etc., in connection with international herpetological meetings. Web address:

<www. teorekol.lu.se/~rana/ISHBH>

Formal application for membership (US $30/regular and $10/student) should be directed to: *Richard Wahlgren, Chairperson, ISHBH, Box 2123, SE-220 02, Lund, Sweden; e-mail: Richard.Wahlgren@skanska.se.*

Phyllomedusa, Journal of Neotropical Herpetology

Phyllomedusa—Journal of Neotropical Herpetology, is a biannual journal dedicated to the study of all aspects of the biology of Neotropical amphibians and reptiles, and is published by Melopsittacus Publiçacões Científicas. Volume 1, Number 1 made its appearance in 2002. Although English is the primary language of the journal, manuscripts will be accepted in Portuguese or Spanish, with English abstracts. The Editor is Jaime Bertoluci (e-mail: bertoluc@icb.ufmg.br). Subscriptions within Brazil: R $20.00; outside Brazil: US $20.00. Correspondence to: *Caixa Postal 1474, Belo Horizonte - Minas Gerais, CEP 30.123-970, Brazil.*

Additional note: Attendees at the 2002 Kansas City meetings

who paid for subscriptions to *Phyllomedusa* need to send their e-mail addresses to Dick Vogt (e-mail: vogt@inpa.gov.br).

Herpetological Collection Moved

The research collection of amphibians and reptiles of the Department of Biology, George Mason University, Fairfax, Virginia (GMU) has been deposited in the Division of Amphibians and Reptiles, National Museum of Natural History, Smithsonian Institution, PO Box 37012, NHB W203, mrc 162, Washington, DC 20013-7012, USA. Please contact Ronald Crombie (e-mail: crombie.ron@nmnh.si.edu) for information concerning specimens.

MEETINGS

Meetings Calendar

25–28 November 2002—VII National Meeting, Sociedad Herpetológica Mexicana (SHM) (Mexican Herpetological Society), Universidad de Guanajuato, México. Information: www.iztacala.unam.mx/shm/.

18–22 June 2003—Second International Congress on Chelonian Conservation in Senegal. Conference to be held in English w/ French translations. Further info: www.tortues.com; e-mail: soptom@soptom.com.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **Omar Torres-Carvajal**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can now be found at: http://www.herplit.com/contents.

Cryptic Patterns in Horned Lizards

Horned lizards of the genus *Phrynosoma* are relatively slow moving animals that utilize crypsis as their primary means of escaping detection. Sherbrooke discusses the vertebral line patterns of two species, which are black in *P. mcalli* and white in *P. cornutum*. The author argues that these lines mimic plant stem shadows and plant stems, respectively. Both species spend large amounts of their daily surface activity underneath clumps of grass, shrubs, and other vegetation. The blotched-spotted patterns of these lizards are consistent with an antipredatory strategy of cryptic defense. Future studies can test this hypothesis in the context of experimental manipulation of vertebral-line patterns, behavioral selection of backgrounds, and geographic variation of these taxa.

SHERBROOKE, W. C. 2002. Do vertebral-line patterns in two horned lizards (*Phrynosoma* spp.) mimic plant-stem shadows and stem litter? Journal of Arid Environments 50:109–120.

Correspondence to: Wade C. Sherbrooke, Southwestern Research Station, American Museum of Natural History, P.O. Box 16553, Portal, Arizona 85632, USA; e-mail: wcs@amnh.org.

Swimming Performance in the Frog *Xenopus laevis*

Numerous studies have failed to demonstrate a trade-off between speed and endurance in locomotor performance of vertebrates. The authors propose two competing hypotheses to explain this phenomenon: 1) the performance trade-off may not pertain to all vertebrates; or 2) trade-off effects of whole muscle may be difficult to observe at the whole-organismal level. These hypotheses were addressed by examining the burst swimming performance and endurance of 55 post-metamorphic *Xenopus laevis*; eighteen of these individuals also were tested for isolated muscle performance with the work-loop technique. Statistical analyses were performed with Pearson's product moment correlation, the Bonferroni method, and student's *t*-test. Results of whole-animal performance experiments indicated no trade-off between measurements of speed and endurance. Isolated whole-muscle performance experiments did not demonstrate any significant correlation between measures of whole-animal performance and *in vitro* muscle performance. However, peak instantaneous power output at six Hz was negatively correlated with the fatigue-resistance of force production at two Hz. It is possible that *in vitro* measures of muscle performance do not accurately reflect *in vivo* locomotor states.

WILSON, R. S., R. S. JAMES, AND R. VAN DAMME. 2002. Trade-offs between speed and endurance in the frog *Xenopus laevis*: a multi-level approach. The Journal of Experimental Biology 205:1145–1152.

Correspondence to: Robbie S. Wilson, Laboratory of Functional Morphology, Department of Biology, University of Antwerp, Universiteitsplein 1, Wilrjk B-2610, Belgium; e-mail: rwilson@uia.ua.ac.be.

Organophosphate and pH Levels of Frozen *Rana sylvatica*

Thawing frogs may experience disruption of vital functions as a consequence of low ATP and creatine phosphate (CP) levels and/or abnormal pH of the blood. The authors used NMR spectroscopy to examine these factors (and inorganic phosphate, P_i) in wood frogs (*Rana sylvatica*) that were exposed to either slow or rapid freezing at -1.5°C for seven days. Statistical tests included repeated measures analysis of variance, Tukey tests, and unpaired *t*-tests. Most of the test subjects survived the slow-freeze treatment (3 of 4), but no frogs survived the rapid-freeze treatment. Levels of P_i increased in both slow and fast-freeze treatments, whereas CP levels declined in both treatments. Levels of ß-ATP were stable in the slow-freeze treatment, but declined in the fast-freeze treatment. Intracellular pH was stable in the slow-freeze treatment, but declined in the rapid-freeze treatment. It is likely that the slow-freeze treatment allowed frogs to maintain sufficient pools of ATP and CP because effective glucose distribution per-

mitted adequate energy metabolism. The likely cause of death in the rapid-freeze test subjects was acidosis.

LAYNE, JR., J. R., AND S. D. KENNEDY. 2002. Cellular energetics of frozen wood frogs (*Rana sylvatica*) revealed via NMR spectroscopy. Journal of Thermal Biology 27:167–173.

Correspondence to: Jack R. Layne Jr., Department of Biology, Slippery Rock University, Slippery Rock, Pennsylvania 16057, USA; e-mail: jrl@sruvm.sru.edu.

Tongue Evolution in the Family Plethodontidae

Many species of plethodontid salamanders have evolved extremely rapid and extendable tongues for the purpose of prey capture. The authors hypothesize that plethodontids with a larval stage of development have experienced a constraint on the evolution of their tongue protraction because of conflicting functions of the hyobranchial apparatus in their biphasic life history. The authors tested the behavioral prediction of this hypothesis—that adult plethodontids will possess poor suction-feeding abilities. This behavior was observed in seven taxa of the subfamily Desmognathinae; all examined species have a life history with an aquatic larva that reorganizes the hyobranchial apparatus during metamorphosis. A total of 275 prey-capture attempts was recorded with a high-speed video camera against a background grid of 5 mm or 1 cm squares. High-quality, videotaped feedings were digitized to facilitate kinematic analyses. Larvae of all examined taxa used suction feeding via hyobranchial depression to capture prey; no animals fed during metamorphosis. Terrestrial-feeding adults used tongue protraction in 32 of 34 feeding attempts, and jaw prehension for the remaining attempts. Aquatic-feeding adults captured prey by lunging forward and grasping prey with the jaws or by tongue protraction—prey were manipulated less effectively in larvae. These results support the authors' contention that the loss of suction feeding in adult plethodontids is a consequence of the evolution of tongue protraction. The evolution of tongue protraction in plethodontids suggests a terrestrial or semi-terrestrial habit was present in ancestral members of this group.

DEBAN, S. M., AND S. B. MARKS. 2002. Metamorphosis and evolution of feeding behaviour in salamanders of the family Plethodontidae. Zoological Journal of the Linnean Society 134:375–400.

Introduced Species of Snakes in Brazil

São Paulo is one of the major commercial centers of southeastern Brazil. The illegal trafficking of exotic and native species of snakes is concentrated in this area. The authors used Sander's Rarefaction Method and data from snakes sent to Instituto Butantan to assess the pattern of new species arrivals in this area. Each species was qualitatively classified for 24 biological categories (e.g., foraging mode) into a niche; niche similarities were estimated using multivariate methods. Twenty-six species of native snakes and 76 species of exotic snakes were included in the investigation. Three main groups (0.2 similarity level) were identified from a cluster analysis of interspecific similarities of biological attributes. The authors point out that some of these species present a potentially lethal threat to humans, and the exotic trade prohibition in Brazil should continue.

ETEROVIC, A., AND M. R. DUARTE. 2002. Exotic snakes in São Paulo City, southeastern Brazil: why xenophobia? Biodiversity and Conservation 11:327–339.

FOR SALE
ORIGINAL WATERCOLORS BY DAVID M. DENNIS

SSAR is pleased to announce the availability of the original watercolor paintings from which the color plates were reproduced in William Duellman's classic book "Hylid Frogs of Middle America." These are one-of-a-kind drawings, two to three times the size of the published versions, and each individually signed by the artist. Prices range from US$100 to $800.

Mr. Dennis is widely recognized as one of the foremost illustrators of amphibians and reptiles. His award-winning natural history paintings have been displayed in major galleries and exhibits and are reproduced in numerous books.

A complete pricelist of the paintings is available on request from the SSAR Publications Secretary, Breck Bartholomew, address: SSAR Publications, P.O. Box 58517, Salt Lake City, UT 84158–0517; e-mail: ssar@herplit.com. Copies of the book in two clothbound volumes ($125) and printed sets of the 46 color plates ($45) are also available from Mr. Bartholomew.

Behavioral Dominance in the Lizard *Cnemidophorus laredoensis*

The *Cnemidophorus laredoensis* complex consists of two sympatric, diploid, all-female parthenogenetic species (LAR-A and LAR-B). Behavioral observations in the field suggest that in aggressive interactions, LAR-B is behaviorally dominant to LAR-A, and that both species defend their burrows from intruders. The author tested these hypotheses in a laboratory setting by placing one individual of each species (approximately the same size) in a 91 x 45 x 54 cm glass aquarium with a cardboard partition that divided the terrarium into two equal sides. The lizards were given 48 hours to adjust to their setting (and dig burrows), and were then filmed two minutes after the partition was removed for 60-min trials. Specific types of behavior dictated whether an interaction resulted in a "winning encounter" for an individual lizard—if an individual "won" more than 50% of the encounters, it was classified as the dominant individual for that trial. Statistical analyses were conducted with Binomial tests, Chi-square tests, Wilcoxon sign rank tests, and conventional *t*-tests. Individuals of the LAR-B species won 13 of 16 trials with clear, overall winners; reproductive state of the lizards did not have an effect on trial outcomes. Individuals of both species did not attempt to defend their burrows from intruders. The discrepancy in burrow-defense behavior in field observations and this study may be an artifact of the experimental design.

PAULISSEN, M. A. Interspecific dominance and burrow use in the two species of the parthenogenetic lizard complex *Cnemidophorus laredoensis* (Teiidae). Southwestern Naturalist 47:21–29.

Habitat Selection of the Wood Turtle *Clemmys insculpta*

Previous models of habitat selection in mobile species assume that an animal's entire home range is available to it between successive observations. However, this assumption does not seem valid for wood turtles (*Clemmys insculpta*) because this species has low mobility and large home ranges. The authors present a model of habitat selection that utilizes samples from one or more random locations paired with each animal location, and a paired logistic regression to analyze the habitat selection. Thirty-seven turtles from western Maine were captured and radio tagged (Lotek MBFT-6 transmitters); these turtles were located by radiotelemetry one to three times per week for several months in the summers of 1997 and 1998, and these data were entered into a geographic information system. Several types of habitat measurements and variables were recorded from activity areas of the turtles. Most of the turtle locations occurred in forest, scrub-forest, bog-fen, or "emergent cover" habitats; males were found in water twice as often as females. Coefficients of the best model from activity-area scales suggest that turtles selected nonforested, low canopy-cover areas that are close to water; overall the models did not demonstrate strong predictive power. A watershed-scale model suggested that turtles select activity areas near streams and rivers with moderate (10–50%) amounts of forest cover—this model had an overall correct classification rate of 84%. The incongruence of models for the different scales is a likely reflection of a trade-off between feeding and thermoregulation.

Fang Formation in Elapid and Viperid Snakes

Previous workers have proposed two conflicting hypotheses to describe snake fang formation. The infolding hypothesis states that embryonic fangs develop an anterior groove that deepens and comes together to form a closed canal. Proponents of the "brick chimney" hypothesis contend that mineralization of hollow fangs proceeds basally without any folding around the canal. Jackson examined a developmental series of fangs from *Naja kaouthia* and *Bitis arietans* with scanning electron microscopy; additional cleared-and-stained specimens of *Crotalus horridus* were examined with light microscopy. Replacement fangs of adult specimens were examined from *Naja melanoleuca, Bothrops lansbergii,* and *Bitis arietans*. Results supported the "brick chimney" hypothesis—shortening of the discharge orifice in viperids may have confused proponents of the infolding hypothesis. Formation and morphology of the first fang in embryonic snakes differed from that of adults and may represent a plesiomorphic condition retained from an opisthoglyphous ancestor.

Effects of Temperature on Eggs of the Scincid *Bassiana duperreyi*

Suboptimal incubation conditions serve as a stimulus for hatching in some species of squamate reptiles. Shine hypothesized that cool temperatures in the montane scincid *Bassiana duperreyi* might stimulate early hatching and produce different phenotypic traits. Eggs were collected from wild nests and transferred to incubators that simulated normal, relatively warm incubation conditions. At various times in the latter half of normal development (7–11 weeks), some eggs were transferred to incubators with either gradual or sudden declines in incubation temperatures—both treatments mimic conditions that have been recorded from wild nests. Locomotor speed of hatchlings was assessed on a one-meter raceway. Hatching success was 73% and 80% for eggs shifted to the "sudden decline" treatment at seven and eight weeks, respectively. All other treatments had a hatching success rate of 93%. Incubation duration was longer for eggs transferred to cooler temperatures at seven weeks, but later transfers had a smaller effect. Longer

incubation periods produced relatively heavy-bodied lizards; locomotor performance was affected by time of egg transfer and the magnitude of temperature decline. Growth was affected in numerous ways by the treatments. Data from other taxa are needed to assess whether these results represent adaptations to local conditions.

Variation of a Peruvian Herpetofauna

Neotropical rain forests are not homogeneous throughout their distribution, and local and regional effects on the herpetofauna in these areas are poorly understood. To understand the effects of microgeographic variation on the herpetofauna of Tambopata Region in Peru, the authors intensively surveyed five localities for 23 months in 1997 and 1998. Each site had four quadrat parcels (80 x 70 m; 56 quadrats each) and two visual encounter survey parcels (1 ha; 24 transects each). During each 18-day visit, 84 quadrats were visited during the night and 24 during the day; each of the visual encounter transects was visited once during the day and once at night. Diversity and similarity between sites was examined with the Shannon-Wiener diversity index and the coefficient of biogeographic resemblance. Revised checklists resulting from this study have distinguished this region of Peru as the most diverse herpetofauna known in the world. Results indicated that many factors are responsible for the herpetofaunal composition in various types of forest, including local hydrography, topography, and soil types.

ZOO VIEW

Approximately fifty years ago, my tolerant parents took me for the first time to the Lincoln Park Zoo in Chicago. There I met Edward J. Maruska, then a keeper in the feline building. Gifted zoo people—brilliant, eccentric, dedicated, often aggressive and controversial, and productive—have always fascinated me and Ed clearly fit this category. Even at this tender age, I recognized his encyclopedic knowledge of the animal kingdom. He was able to field every question I posed with ease and he spent many hours instructing me about animal diversity, captive animal management, and the vagaries of the zoo profession.

Later, soon after I was miraculously accepted as an undergraduate student at Xavier University in Cincinnati, Ed was offered the position of Assistant Director at the Cincinnati Zoo and Botanical Garden. When his boss left to become director at another zoo, Maruska was elevated to the top post. Ed embraced this challenge but was faced with a zoo in a deplorable state: outmoded and inadequate exhibits, many poorly trained keepers, organizational instability, substandard animal collection, political pressure, low visitation, and public indifference. One example of shoddy keeper training will illustrate the lack of professional standards. Shortly after Ed arrived at the Zoo, he watched in amazement and horror as a keeper washed the concrete floor of a cage containing a huge adult male baboon. The primate grabbed the hose, pulled the keeper across the enclosure, bared his enormous canines and screamed in his face, then held the keeper's shoulders firmly and shook him violently for many minutes. During the whole episode, Ed yelled at the keeper to vacate the cage immediately. Shaken and concerned, Maruska asked the keeper upon exiting if he had been traumatized or injured. The employee responded that he was just fine and Ed need not worry; this ritual had been a daily occurrence for years! Because Ed is an energetic fellow, he plowed his considerable talents into improving the Zoo. Today, this institution is considered to be one of the world's finest.

When the annual SSAR meeting was held in nearby Miami, Ohio many years ago, a tour of the Zoo was scheduled for the attendees. Prominent amphibian biologists from the museum and academic community had heard that Maruska had amassed a salamander collection but they were not prepared for the width and breadth of this caudate assemblage. Salamanders were housed in every nook and cranny throughout the Zoo. As they viewed olms, giant salamanders, rare cave salamanders, and other exotic forms infrequently seen alive, their collective impression was one of awe. Because Ed is a talented photographer, he had created dioramas using living ferns, mosses, lichens, mushrooms, and other plants to be used as a backdrop for photographing his specimens. In addition, there was an extensive preserved collection as Ed was fastidious about maximizing the use of this collection by recording locality data. Many colleagues told me that this was without doubt the most overwhelming living salamander collection ever assembled!

Maruska published a number of papers outlining his procedures for setting up and maintaining his salamander colony (see Maruska 1994. *In* J. B. Murphy, K. Adler, and J. T. Collins [eds.], Captive Management and Conservation of Amphibians and Reptiles, pp. 229–242. SSAR. Contributions to Herpetology, volume 11 for an example.). Because the salamander collection is so diverse and comprehensive, an impressive number of longevity records have been compiled and many husbandry and medical protocols developed. In the second edition of "Longevity of Reptiles and Amphibians in North American Collections" (SSAR Herpetol. Circ. No. 21), 66 taxon-records derive from the Cincinnati Zoo collection. Salamanders of 32 species lived over 10 years and of these, five passed 20 years. This is a remarkable accomplishment. According to "International Zoo Yearbook" (1998:Volume 28), composition of the collection was 97 taxa of reptiles with 365 specimens and 66 taxa of amphibians numbering over 560 specimens.

Because Ed is a collector par excellance, a visit to his zoo office was always an adventure. Piles of books, photographs, posters, zoo memora-

bilia, artifacts from his world travels such as weapons, statues, carvings, and a myriad of other objects, littered this room; in fact, he had to clear part of the accumulation off a chair so I could sit during my last visit. When I mentioned that his collecting impulse was beyond control, he said that his home was stuffed to the breaking point with many more of his treasures.

I have a special warm feeling for him as he was my mentor, advisor, confidant, and friend throughout my career; although now retired, his influence in our profession was and is still likely to be profound.

During the Third World Congress of Herpetology in Prague, Czech Republic in 1997, I first met Hans-Werner and Patricia A. Herrmann. Patricia, whose maiden name was Mahaney at that time, worked at the Arizona-Sonora Desert Museum. They discovered each other there as well and founded their relationship in this professional setting.

Although we had not interacted earlier, Hans-Werner's reputation was widespread for he had established an enviable research and conservation program at the Cologne Zoo where he was curator. I had been impressed with his publications on viperid phylogeny and knew of his herpetofaunal surveys in Cameroon and Vietnam so the chance to ask him in person about his herpetological activities was welcome.

Last year, they traveled to Washington, D.C. and came to my abode for a few glasses of wine and dinner. Hans-Werner pulled a sizeable pile of photographs from his briefcase and asked if I would like to see them. I assumed that these would be wedding or honeymoon photos but, alas, it should have been apparent that herpetologists more often have photos of amphibians and reptiles. In this case, the images were of his newly described Vietnamese horned pitviper *Triceratolepidophis sieversorum*, as well as the rare *Trimeresurus cornutus*, photographed from every conceivable angle.

To pursue his love of field research, Hans-Werner left the Cologne Zoo earlier this year to embark on an exciting new adventure. He and Patricia will continue to study the biology of the endangered goliath frog in Cameroon, sponsored by the Center for the Reproduction of Endangered Species at the San Diego Zoo. I asked if they would share highlights of their earlier time in Cologne and their account follows.

The Cologne Zoo was founded in 1860; it is the third oldest zoo in Germany. The aquarium building was added over a century later in 1971. This building follows in the German zoo fashion of building so-called "exotariums" or "vivariums" in which amphibians and reptiles, but also fishes and invertebrates, are housed. Cologne's zoo, together with the aquarium, was voted the "Number 1" zoo in Germany by the prominent Stern news magazine in 2000. There are about 100 species of herpetofauna. Breeding is an integral part of the collection's husbandry policy. Examples of noteworthy breedings are *Palaeosuchus palpebrosus*, *Cyclura cornuta*, *Chamaeleo* spp., *Chelodina oblonga*, *Holaspis leavis*, and several dendrobatid species.

In 1998 an important new direction was founded in the Cologne aquarium. In situ biodiversity conservation activities were commenced in Cameroon with corporate sponsorship by the German branch of the American Linen Supply Company (ALSCO), and the Zoo Cologne Nature Conservation project was started in Vietnam. The latter project presently is run as an in situ activity affiliated with the new rainforest house at the zoo. Nevertheless, the initiation of this project and a large portion of the actual in situ work has been carried out by aquarium staff.

The ALSCO Biodiversity Conservation Initiative in Cameroon was started in 1998 at Mt. Nlonako, a mountain rainforest area in the vicinity of Nkongsamba, Southwest Cameroon (Herrmann et al. 1999). First herpetological surveys (see also Herrmann et al. 2000; Kolter et al. 2001) have produced a total of more than one hundred species including such enigmatic representatives as the Goliath frog (*Conraua goliath*), the hairy frog (*Trichobatrachus robustus*), and the rare Pfeffer's chameleon (*Chamaeleo pfefferi*), known from the female type specimen only for about one hundred years.

As a result of the teaching commitments of Cologne Aquarium staff at the Department of Biology, Philipps-University Marburg, graduate students are currently conducting amphibian ecology research within the framework of the conservation activities. One goal of this work is to obtain baseline data on amphibian species ecology in tropical Africa to be used to analyze the African situation within the global perspective of declining amphibian populations. In the future the study of the ecology and conservation biology of selected anuran species as well as their possible value as biological indicators will be additional focal points of the project.

Conraua goliath as bushmeat offer.

Triceratolepidophis sieversorum portrait showing supraocular horns.

The ALSCO biodiversity conservation activities are also focused on the Tchabal Mbabo area, a particularly isolated mountain rainforest relict in the Adamaoua plateau region of Western Cameroon adjacent to the border of Nigeria. This area is one of the northernmost rainforests in Africa and shows a fair degree of endemism including the recently described caecilian *Crotaphatrema tchabalmbaboensis* (Lawson 2000). Due to the remoteness and inaccessibility of this region, only initial surveys have been conducted thus far.

In 1999 Cologne Zoo began its involvement with the conservation of the Phong Nha Nature Reserve in Quang Binh province in Central Vietnam (Herrmann and Pagel 2000). This karst mountain area is situated in the Annamite mountain range, which runs along the Vietnam-Laos border and is remarkable for a number of newly discovered and endemic large mammal species (i.e. *Pseudoryx nghetinhensis*, *Megamuntiacus vuquangensis*, *Nesolagus timminsi*). The area has revealed 96 different amphibian and reptile species (Ziegler and Herrmann 2000). Recent investigations have uncovered additional species which increases the total number to well over one hundred species. The most spectacular finding was a hitherto unknown genus and species of large crotalid, which was subsequently described as *Triceratolepidophis sieversorum* (Ziegler et al. 2000). Recently the Phong Nha area together with the adjacent Ke Bang area were elevated to the Phong Nha-Ke Bang National Park by the Vietnamese government.

All the above-mentioned areas and their biodiversity are threatened by habitat loss and fragmentation due to encroachment and logging. Poaching for the bushmeat market and traditional medicine practices plays an important role in population declines. In these projects we are sensitive to the close relationship between sociological aspects and conservation; involvement of local communities in all levels of fieldwork and education is vital. Close associations with the conservation authorities and local universities and researchers are maintained.

Acknowledgments.—We thank Jim Murphy for his invitation to contribute to this column. We are grateful to those staff members at the Cologne Aquarium, without whose enthusiasm and help neither the husbandry nor breeding of amphibians and reptiles would have been possible. Special thanks goes to ALSCO Germany, namely Mr. Horst Nobis, who almost exclusively financed the Zoo Cologne Cameroon conservation activities. The Cameroonian Ministries of Scientific and Technical Research (MINREST) and Environment and Forestry (MINEF) issued permits and supported our activities at Mt. Nlonako and Tchabal Mbabo. In Vietnam we received support from the Hanoi Center for Natural Resources Management and Environmental Studies (CRES), the Forest Planning Department (FPD) and the Peoples Committee of Quang Binh. Last but not least, we wish to thank all our enthusiastic and capable students and colleagues in Cameroon, Vietnam, and elsewhere for their companionship and assistance.

Project Golden Frog Clarification

In the March 2002 issue of *HR*, the inaugural edition of the Zoo View column featured the Detroit Zoo's National Amphibian Conservation Center and its most high-profile program, *Project Golden Frog*. In attributing authorship of the project summary to NACC staff, the section editor inadvertently gave the impression that PGF is a Detroit Zoo initiative. On the contrary, PGF began in 1997 as a collaboration between the Columbus Zoo and then-Ohio State University doctoral candidate Erik Lindquist. Since that time, Dr. Lindquist has relocated to Lee University, and staff/research associates at the Smithsonian Tropical Research Institute, Círculo Herpetológico de Panamá, Baltimore Zoo, and Detroit Zoo have also taken on leadership roles and have greatly contributed to all aspects of the Project. Project Golden Frog is truly a multi-institutional initiative whose success is entirely dependent on the diverse experience and insight of its co-PIs. We apologize for the inadvertent oversight in recognition.

The Relationship Between Mass and Snout–Vent Length in the New Zealand Tor-Inhabiting Skink *Oligosoma grande*

ALLEN E. GREER
Herpetology Section, Australian Museum
6 College Street, Sydney, NSW 2010, Australia
e-mail: alleng@austmus.gov.au

and
TONY WHITAKER
R.D. 1, Motueka 7161, New Zealand
e-mail: whitaker@ts.co.nz

Considering the significance of mass as a covariate of other morphological and ecological variables, it is remarkable how little information and analysis there is for this fundamental parameter in many species of squamates. For example, there are analyses that address the issue of the allometric relationship for mass on snout-vent length in only two of the some 1252 species of skinks: *Eumeces laticeps* (Vitt and Cooper 1985) and *Mabuya heathi* (Vitt 1995).

During the course of field work on the New Zealand tor-inhabiting skink *Oligosoma grande* in the Macraes Flat area of the South Island in the period January 1994 to April 1995, one of us (TW) gathered data on mass (to nearest 0.5 g with Pesola™ spring balance), snout–vent length (to nearest 1 mm by hanging the relaxed live skink against a metric ruler), and sex (where feasible by eversion of tail base). No specimens were taken due to the fact that the species is one of New Zealand's most severely threatened species. The data were presented graphically in the resulting technical report (Whitaker 1996:Fig. 2), but no further analysis was undertaken. Here we analyze these data further, especially with regard to the relationship between mass and snout–vent length. Statistical anaylsis was carried out with Systat 9 software.

There is a strong sexual dimorphism in this species, with females attaining much larger snout–vent lengths and greater masses, although part of the greater mass in females might be because of the virtual certainty of some being gravid. Snout–vent length in sexable males ranged from 66 to 101 mm (mean = 88.3 mm, SD = 8.84, N = 40) and in sexable females from 81 to 109 mm (mean = 98.1 mm, SD = 5.19, N = 41)(Mann-Whitney = 1383, $P < 0.001$). Mass in males ranged from 5.8 to 22 g (mean = 14.9 g, SD = 4.37, N = 40) and in females from 9.5 to 29.0 g (mean = 19.4 g, SD = 3.90, N = 41)(Mann-Whitney = 1239, $P < 0.001$).

The relationship between mass and snout–vent length in each sex was examined by regression analysis of the log transformed data (in order to make the relationship more nearly linear). The regression line for log mass on log snout–vent length for the sexable males has the equation: log mass = –4.76 + 3.04 log snout–vent length ($P < 0.0001$, $r^2 = 0.93$, N = 40). The regression line for the sexable females has the equation: log mass = –5.16 + 3.23 log snout-vent length ($P < 0.001$, $r^2 = 0.73$, N = 41)(logs base 10)(Fig. 1). The 95 percent confidence intervals for the slopes for the two regressions are ± 0.28 and ± 0.62, respectively, both intervals confidently include the slope indicative of isometry: 3.00. The reason that more of the variance in mass is explained by snout–vent length in males (0.93) than in females (0.73) and the confidence interval for the slope is smaller in males (± 0.28) than in females (± 0.62) is again, in part, because of the likelihood of some females being gravid. The regression for log mass on log snout–vent length for all specimens combined (sexed and unsexed) has the equation: log mass = –4.89 + 3.10 log snout-vent length ($P < 0.0001$, $r^2 = 0.99$, N = 184). The 95 percent confidence interval for the slope is ± 0.05 suggesting a relationship of mild positive allometry. That this positive allometry is not just because of the probable inclusion of gravid females is indicated by the positive allometry for all individuals exclusive of sexable females. The equation is: log mass = –4.96 + 3.14 log snout–vent length ($P < 0.0001$, $r^2 = 0.99$, N = 0.99, N = 143). The 95 percent confidence interval for the slope is ± 0.06 suggesting, again, a relationship of mild positive allometry. Therefore, we take the regression for log mass on log snout-vent length for all specimens as indicative for the species (Fig. 2).

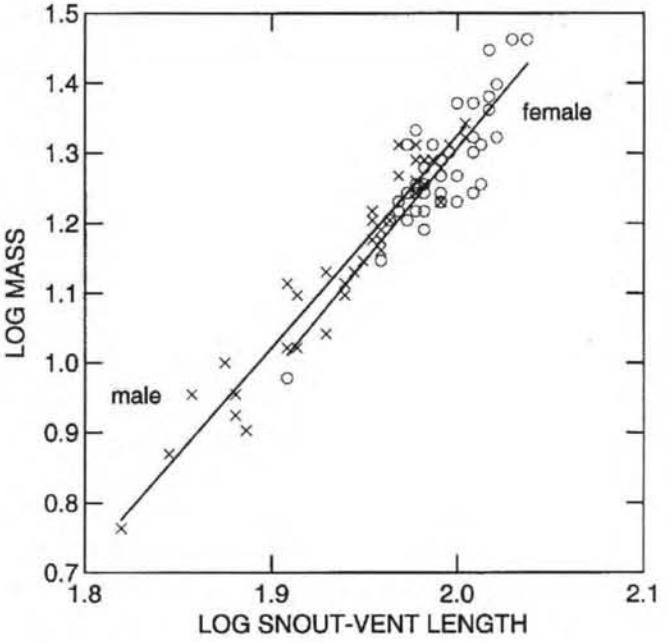

FIG. 1. Regression for log mass on log snout–vent length for the sexable specimens of male (X) and female (O) *Oligosoma grande*. Regression equation for males: log mass = –4.76 + 3.04 log snout–vent length ($P < 0.0001$, $r^2 = 0.93$, N = 40) and for females: log mass = –5.16 + 3.23 log snout–vent length ($P < 0.001$, $r^2 = 0.73$, N = 41).

The regression lines for the log mass on log snout–vent length for each sex were compared by analysis of covariance (ANCOVA) to find differences in the slopes of the two lines and if not, then for a difference in the intercepts (elevations) of the two lines. This analysis showed there was no significant difference between the sexes in the slopes ($F = 0.34$, df = 77, $P = 0.56$) and a barely nonsignificant difference in the intercepts ($F = 3.69$, df = 78, $P = 0.058$)(Fig. 1). This comparison of the two lines was permitted because the residual variances around the regressions were not significantly different ($F = 1.40$, df = 39,38, $P > 0.05$). If the difference in intercepts were to be taken as significant, males could be interpreted as being heavier for their length than females.

In most skinks, females are larger than males in snout–vent length

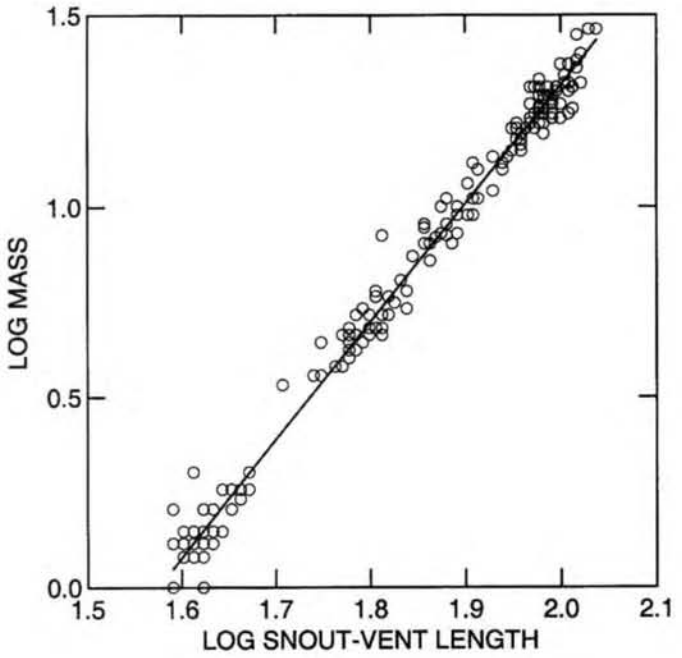

FIG. 2. Regression for log mass on log snout–vent for both sexed and unsexed specimens of *Oligosoma grande*. Regression equation: log mass = –4.89 + 3.10 log snout–vent length ($P < 0.0001$, $r^2 = 0.99$, $N = 184$).

(Fitch 1981; AG, pers. obs.), although in some species males are larger than females, e.g., *Eumeces laticeps* (Vitt and Cooper 1985). With females larger than males, *Oligosoma grande* is typical of most skinks.

The relationship between mass and snout–vent length shows negative allometry in male *Eumeces laticeps* (Vitt and Cooper 1985:Table 1 where the slope is 2.34 and the 95 percent confidence interval is ± 0.46) and isometry in female *E. laticeps* (Vitt and Cooper 1985:Table 1 where the slope is 2.72 [not the misprinted 0.72, L. Vitt, pers. comm.] and the 95 percent confidence interval is ± 0.52) and in both sexes combined in *Mabuya heathi* (Vitt 1995:Appendix I where the slope for mass$^{1/3}$ is 1.004 and the 95 percent confidence interval is ± 0.03). Our finding of positive allometry for both sexes combined in *Oligosoma grande* thus adds another form of allometry for the mass on length relationship in skinks. Why this species should "bulk up" disproportionately (albeit slightly) as it increases in size is unclear. Male combat might not be the answer because male *Eumeces laticeps* are one of the most combative groups of skinks (Vitt and Cooper 1985), and yet they become relatively less bulky with size (above). Clearly more data on mass and length relationships are needed before any phylogenetic or ecological trends emerge.

Status of Larval Identities Among the Peninsular Malaysian Anura

TZI MING LEONG
Department of Biological Sciences, National University of Singapore
Singapore 119260, Singapore
e-mail: scip0132@nus.edu.sg

As a result of the rapid increase in tadpole research, the basic need for the proper identification/characterization of anuran larvae could never be greater (Altig and McDiarmid 1999). For Peninsular Malaysia, the most concerted research effort with particular emphasis on tadpoles was by Berry (1972), who described eight species in careful detail. Despite demonstrating her competency in accurate tadpole descriptions, she did not incorporate larval characteristics in her reference book published later (Berry 1975). Moreover, a number of earlier larval descriptions had already been published for various Malaysian species. However, because of its proximity (past connections across the Sunda Shelf) with neighboring land masses (e.g., Sumatra, Java, Borneo), Peninsular Malaysia shares many anuran species with these regions, and has a relatively low incidence of endemic species (Inger 1999). Thus, a compilation of larval descriptions (not strictly from the peninsula) of anuran species of Peninsular Malaysia would provide a clearer overall picture as to the status of their true identities, and also point out the direction in which heightened research efforts should be channeled.

After a comprehensive literature search, an updated species checklist of the Peninsular Malaysian anurans was produced (Table 1). Each species was numerically scored according to the certainty/thoroughness of its larval assignment/description. The scores range from 0 to 2.0, where 0 – unknown; 0.5 – known, with uncertainty; 1.0 – basic, minimal description/illustration; 1.5 – more detailed descriptions/illustrations; 2.0 – detailed descriptions/illustrations plus internal oral morphology; 0* – in the process of being described; DD – Direct Development. Where applicable, respective references are included and arranged in chronological order. Since Berry (1975), new species have been described and name changes have occurred at the familial, generic, and species levels. The present nomenclature of the species in Table 1 is in accordance with Appendix 8:1 of Inger (1999). A total of 88 species are listed. The five families represented are Bufonidae (14 species), Megophryidae [previously Pelobatidae] (8 species), Microhylidae (18 species), Ranidae (30 species), and Rhacophoridae (18 species). In his checklist, Kiew (1984c) published the names of four species (*Rana cryptica*, *Rana paludicola*, *Kalophrynus leucovitellus*, and *Kalophrynus silus*) seemingly occurring in Peninsular Malaysia. As there was virtually no detailed description of the species named, all four should be effectively regarded as *nomena nuda*, and considered invalid (R. Inger, pers. comm.).

Among the 88 species listed, 71% of the bufonids, 88% of the megophryids, 83% of the microhylids, 77% of the ranids, and 56% of the rhacophorids have their larval identities known with certainty (scores of 1.0, 1.5, or 2.0). Hence, by focusing on the species with scores of 0 and 0.5, progressive efforts might be made to eventually elucidate their hidden identities.

TABLE 1. Peninsular Malaysia Tadpole Status Checklist (0 – Unknown; 0.5 – Known, with uncertainty; 1.0 – Basic, minimal description/illustration; 1.5 – More detailed descriptions/illustrations; 2.0 – Detailed descriptions/illustrations plus internal oral morphology; 0* - In the process of being described; DD – Direct Development).

Microhabitat Selection in *Porthidium nasutum* (Serpentes: Viperidae) in Costa Rica, with Comments on Ontogenetic Variation

TODD A. CASTOE*
Department of Biology, The University of Texas at Arlington
Arlington, Texas 76019-0498, USA

**Present address:*

The rainforest hognosed pitviper, *Porthidium nasutum*, is an inhabitant of the humid tropical lowlands of Middle America and northwestern South America, belonging to the Eastern Mesoamerican Complex of Savage (1966) and the Humid Tropical Assemblage of Duellman (1966). The range of *P. nasutum* includes most of the lowland rainforests of Middle America as well as Colombia and Ecuador (see Campbell and Lamar 1989, for detail). Throughout its range, this species occurs from near sea level to about 900 m in elevation, but is generally found below 600 m (Porras et al. 1981).

Despite its relatively high abundance in Costa Rica (pers. obs.), little has been reported on the behavior and ecology of this species. According to Porras et al. (1981), *Porthidium nasutum* is terrestrial and nocturnal, although specimens can be found basking by day. Based on a review of previous work on the species, Porras et al. (1981) report specimens having been found inside cavities in the trunks of trees, underneath roots of trees or rocks, under logs, among loose rocks of archaeological ruins, or lying on the forest floor. Campbell (1998) stated that while this species is considered nocturnal, it is most often found in the early mornings crossing jungle paths or roads, or lying coiled in leaf litter in small patches of sunlight. He stated that encounters are most frequent in primary forest or in small patches of secondary forest surrounded by primary forest. In this study, microhabitat preferences and activity patterns of *P. nasutum* were investigated by examining environmental features and behavior of this species in a wet tropical forest in northeastern Costa Rica.

Methods.—Snakes were located through visual encounters along trails in the three major forest tracts of Estación Biológica La Suerte (Limon Province, northeastern versant of Costa Rica) in July of 1999. These tracts are a mosaic of primary and secondary tropical wet forest. The age class of each snake was recorded as adult (> 30 cm) or sub-adult (< 30 cm) based on overall body length. Individuals (N = 6; 3 adults, 3 sub-adults) were uniquely identified based on color pattern. Observations were conducted during daylight hours as well as at night (using a low luminosity red lamp).

The area immediately surrounding each individual snake was

surveyed for characteristics possibly influencing microhabitat selection. The distance from the snake to the trunk of the nearest buttressed tree (> 0.5 m in diameter) was recorded to the nearest 0.5 m. The area within a 0.5 m radius of the snake was surveyed for placement of woody structure of debris (> 5 cm in height). Leaf litter depth was recorded in close proximity to each individual by measuring 5 randomly selected points within 0.5 m of each snake. The location of each snake was plotted on maps of the forest and used to identify the closest stream to each occurrence. The estimated snake-to-stream distance was later ground-truthed to the nearest meter in the field. The data collected for leaf litter depth, snake-to-stream distance, and snake-to-buttressed tree distance were analyzed using a Mann-Whitney U test to determine significant differences between age classes. The presence or absence of woody structure within a 0.5 meter radius was analyzed using a sign test. Results of the microhabitat measurements were summarized as means with standard errors and are presented in Table 1.

TABLE 1. Summary of quantitative habitat/microhabitat selection data for *Porthidium nasutum*. Microhabitat measurements for sub-adults, adults, and overall are reported as means ± standard error. (* Indicates statistically significant differences between adults and sub-adults).

	Adult	Sub-adult	All	Sub-adult vs. Adult P-value
Distance from nearest butressed tree (m)	1.8 ± 0.88	7.3 ± 1.76	4.3	0.513
Leaf litter + humus depth (cm)	1.7 ± 0.53	1.3 ± 0.33	1.5	0.421
Percentage of snakes with woody structure present within 0.5 m radius	33.3%	100.0%	66.6	0.480
Distance from nearest stream (m)	43.3 ± 3.33	22.7 ± 2.33	33	0.043*

Results and Discussion.—The results of this study demonstrate the first quantitative microhabitat data reported for this species (Table 1), which includes previously unreported ontogenetic variation in microhabitat selection. While the first three tests were not significant, the data show a significant ontogenetic difference relative to distancing from streams (Table 1). On average, sub-adult snakes were found 15.6 m closer to streams than were adults. Similar ontogenetic shifts in snake to stream distance have been reported in *Bothrops atrox* in Venezuela and are thought to be linked to the micro-geographic structuring of prey communities at varying distances from these streams (Reinert 1993, Sexton 1957).

Several ontogenetic differences associated with the morphology of this species give reason to suspect ontogenetic differences in microhabitat choice. Porras et al. (1981) reported that specimens show ontogenetic shifts in color pattern, with juveniles being more distinct and brightly colored than adults, especially with regard to the mid-dorsal stripe which fades or disappears in adults (Porras et al. 1981). Increasing size also leads to the fragmentation of blotches that often gradually divide into two portions, laterally displaced from the mid-dorsal line (Porras et al. 1981). Such apparent morphological differences might represent adaptive features which facilitate ontogenetic microhabitat shifts reported in this study.

To date, information on the diet of this species is available only as anecdotal accounts. Campbell (1998) stated that adults of this species in Guatemala feed mostly on frogs and lizards as well as small rodents, while juveniles are known to feed on invertebrate prey. Porras et al. (1981) reported the diet to include lizards and mice, in addition to juveniles eating earthworms in captivity. Greene (1997) reported that juveniles of this species commonly feed on frogs and lizards while adults consume mostly mammals and the occasional bird. Additionally, *Porthidium yucatanicum* and *Cerrophidion godmani* (members of the "*Porthidium* group" sensu Burger 1971), show a similar ontogenetic shift as juvenile diets focus on invertebrates, frogs and lizards, while adults of both species shift to mammalian prey (Campbell and Solórzano 1992; McCoy and Censky 1992). The preliminary data on microhabitat partitioning in *Porthidium nasutum* presented here might be associated with such ontogenetic shifts in diet.

Acknowledgements.—I would like to thank Chuck Cohout, Rick Constantino, Ron Bonnet, and Chaz Gilbert for help in the field, and Ron Bonnet, Tiffany Doan, Tom LaDuke, Walter Schargel, and Eric Smith for discussion of the results and comments on early drafts.

Notes on the Effects of *Trimorphodon biscutatus* Venom on a Human

DANIEL H. FOLEY III
Department of Biology, Utah State University
Logan, Utah 84322-5305, USA
e-mail: wildlife@biology.usu.edu

Approximately 2500 species of snakes have been described, the majority (~ 70%) of which belong to the family Colubridae, of which the systematics is largely unresolved (Pough et al. 2001). There is considerable variation in maxillary dentition among colubrids. Moreover, the variation in tooth size and extent of groove is nearly continuous among colubrids. Nevertheless, general distinctions are made among colubrids with or without grooved rear teeth. Many species of colubrids possess solid teeth, without grooves (aglyphous) or connections to venom glands. Other species possess grooved rear teeth (opisthoglyphous) situated below a supralabial Duvernoy's gland, specialized to produce venom (Rodríguez-Robles 1994). Colubrids are generally considered nonvenomous; however, possibly half are capable of producing toxic secretions from their Duvernoy's gland (Gans 1978). Moreover, 40 species have been recorded as capable of producing toxic effects in humans or other animals (Brown 1939; Gans 1978; McKinstry 1978), four of which have caused human fatalities. Opisthoglyphous snakes inject venom by masticating prey, allowing the venom to be channeled down the grooves of the enlarged rear teeth.

Trimorphodon biscutatus possess an opisthoglyphous dentition with associated Duvernoy's glands. Hill and Mackessy (1997, 2000) tested the venom yields from 12 species of opisthoglyphous colubrids. Among those tested, *Trimorphodon biscutatus* possessed the fourth largest average venom yield (130 ml) with an average of 6.34 mg of dry venom yield per strike. Among the seven North American species tested, *T. biscutatus* produced the largest venom yield. Understanding the effects of this species' venom on humans is therefore important. Scant information is available documenting envenomation effects. However, here I report the effects of an induced bite from a *T. biscutatus* on a human.

On 28 April 2000, an adult male *Trimorphodon biscutatus* (SVL ~ 550 mm) was collected from the Black Mountains in Mohave County, Arizona, USA, 7.2 km east of the Oatman Rd./US Route 66 junction. The following evening the snake was induced to bite and the observations below recorded. The specimen was eventually preserved and deposited with the University of Texas at Arlington collection of vertebrates (UTAR 50702).

29 April 2000, 1849 h: the snake was induced to bite the second joint of the left outer finger. Once the snake grasped the finger it immediately began making chewing motions and copious amounts of a saliva-like substance were visibly oozing from its mouth. The snake was allowed to continue its chewing motion for approximately 30–45 seconds, after which the snake was forcefully removed from the finger. A thick layer of a saliva-like substance completely covered the bite site, and a small amount of blood flowed from two distinct punctures (Fig. 1). 2 min: a stinging sensation was noticeable within the bitten finger. 5 min: a whitish ring formed around the distal most fang puncture, and minor swelling of the finger was apparent. 7 min: the entire finger had the sensation of being hot and began to itch. 8 min: swelling continued to progress within the entire finger. 11 min: the proximal fang puncture site showed noticeable swelling and was raised slightly above the surrounding tissue. 17 min: swelling of the bitten finger continued so that the finger felt tight and normal flexion was reduced. 22 min: swelling not spreading into hand; pain continues within finger with distinct throbbing sensation. However, the injury is not extremely painful. The sensation is similar to that experienced by a wasp or scorpion sting. 47 min: throbbing sensation ceased and pain subsided; finger still very swollen, tight and inflexible. 1 h 10 min: swelling subsided, enough to allow finger to be fully flexed. 2 h 07 min: swelling reoccurred so that finger can now only be flexed about half of normal. 2 h 39 min: no change in amount of swelling; still only capable of bending finger about half of normal. 4 h 19 min: finger still with sensation of being tight and still noticeably swollen; can only be bent approximately 3/4 of normal. 30 April 2000, 12 h 40 min: finger slightly swollen at base; can now be bent fully. However, this action causes a very slight pain.

Although experiments have shown that the venom of *Trimorphodon biscutatus* is capable of killing small lizards (Cowles and Bogert 1935), the effect on humans seems to be rather minimal with regard to this case report. Localized pain and swelling can result from bites in which the snake is able to chew for an extended period of time, although this seems improbable during normal field encounters. It must be stressed that all protein-based

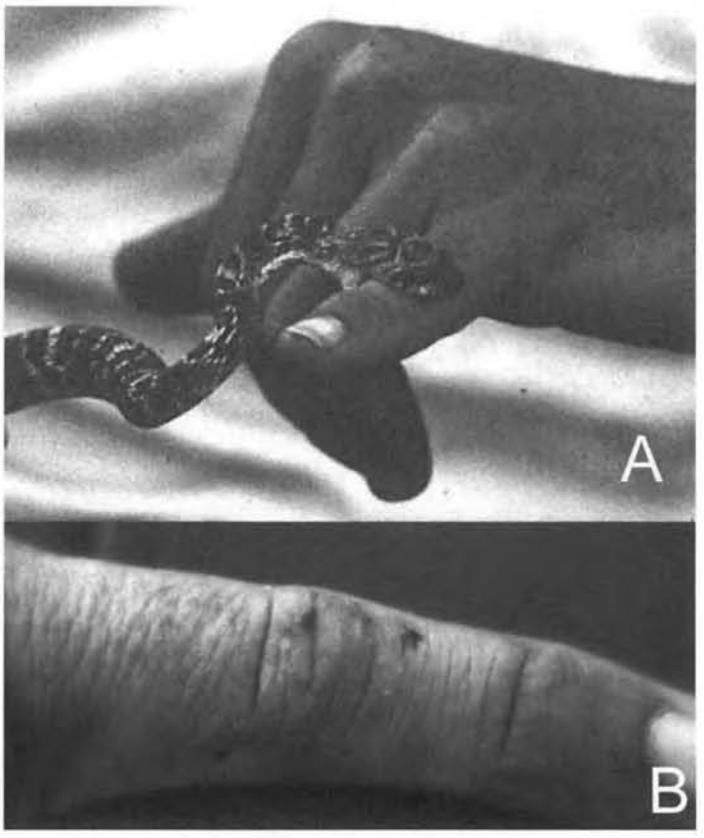

FIG 1. Photographs showing (A) the envenomation and (B) the resulting puncture wounds.

venoms might carry the risk of anaphylaxis and other severe allergic reactions. Therefore, it is best to use caution when handling any species of rear-fanged snake.

Acknowledgments.—I thank K. Setser and P. C. Ustach for assistance in the field while I documented the unknown effects of this envenomation. The photographs were taken by K. Setser. This manuscript benefited greatly from the suggestions and comments of E. D. Brodie, Jr., J. R. Mendelson III, S. P. Mackessey, the USU Herpetological Study Group, and three anonymous reviewers.

Some Observations of the Natural History of the Prehensile-tailed Skink, *Corucia zebrata*, in the Solomon Islands

LUKE J. HARMON*
Sir Dudley Tuti College, Kamaosi, Bugotu District
Santa Isabel, Solomon Islands

**Current address: Department of Biology, Campus Box 1137*
Washington University, St. Louis, Missouri 63130-4899, USA
e-mail: harmon@biology.wustl.edu

The prehensile-tailed skink, *Corucia zebrata*, is endemic to the Solomons archipelago in the southwestern Pacific, occurring on the Solomon Islands as well as on adjacent islands in the North Solomons province of Papua New Guinea (McCoy 2000; Parker 1983). *Corucia zebrata* is a large, unique arboreal species of skink with an unusual caudal anatomy (Zippel et al. 1999). It is the only truly herbivorous member of the Scincidae (Iverson 1982). Much previous work on *C. zebrata* comes from captive animals, with limited information available from wild populations (Hediger 1937; Honegger 1975; McCoy 1980; Parker 1983). The species might exhibit communal torpidity (Kinghorn 1928), as observed in the related genus *Egernia* in Australia, but this behavior has yet to be confirmed in the field. Skinks from different islands in the Solomons archipelago differ significantly in coloration, morphology, and diet (Köhler 1997; McCoy 2000; Schmidt 1991), and a new subspecies (*C. z. alfredschmidti*) was recently described from populations on Bougainville (Köhler 1997). I studied the natural history of wild *Corucia zebrata* from a little-known population in the Bugotu district of Santa Isabel, Solomon Islands. In this report, I present additional data and anecdotal information on the morphological characteristics, life history, and reproduction of *C. zebrata* from this natural population that corroborate captive observations. Furthermore, I present data on communal living habits of these skinks in the wild, along with evidence of previously unreported sexual dichromatism in the Isabel skinks. This study adds to the limited knowledge of the natural history of wild *C. zebrata*, information that might be useful in conservation efforts for this potentially threatened species.

The study area was primary rainforest bordering the Sir Dudley Tuti College school compound, located about 2 km inland from Kasera Bay in southeastern Santa Isabel (159°48'E, 8°28'S). Along with student field assistants, I located lizards by searching primary rainforest areas and identifying potentially suitable habitat—large trees with extensive epiphytic growth (Parker 1983). Additionally, the distinctive smell of the feces of *Corucia zebrata* (Honegger 1985) was used to locate trees in which individual animals resided; this is the first documented use of olfactory cues to locate skinks in the wild. If a *C. zebrata* was present in the vicinity, the smell of its feces was apparent, even at ground level, to an experienced observer. Several local students skilled in locating these animals by smell assisted me. Once a promising location was found, nearby trees were climbed and actively searched by student field assistants.

Data collected on all captured skinks included mass, snout–vent length (SVL), total length, coloration, and characteristics of the capture site, including height of the hole above ground, type of tree, and presence or absence of surrounding vines. Sex was determined by eversion of hemipenes. Captured skinks were marked with unique combinations of toe clips and released at the original site of capture. Sizes of each sex were compared using a t-test with separate variance, conducted using SYSTAT 7.0 for Windows (SPSS 1997). Additionally, two females were dissected to determine reproductive status and examine stomach contents.

Twelve skinks were examined: five adult males, three adult females, two juveniles, and two adult lizards whose sex was uncertain. No skinks were recaptured. Measurements of the adult skinks were similar to those reported in previous studies (N = 10; means ± SD: mass = 716 ± 53 g, SVL = 29.3 ± 2.7 cm, total length = 64.9 ± 3.9 cm). The juvenile captured in late August 1999 (150 g, 17.9 cm SVL, 37.3 cm total length) was slightly larger than the reported sizes for newborn *Corucia zebrata* (Honegger 1975; Parker 1983; Schmidt 1991), while the second, caught in early October 1999, was larger (290 g, 23.8 cm SVL, 49.0 cm total length). The sex of these two juvenile skinks could not be determined. Adult females were significantly larger than males in mass ($p = 0.006$), nearly significantly larger in SVL ($p = 0.053$), and not significantly different in total length (Table 1). This difference in mass is likely because of the fact that at least two of the three adult females were gravid when caught.

TABLE 1. Sexual size dimorphism in *Corucia zebrata* on Santa Isabel, Solomon Islands. P-value from t-test with separate variance.

	Male Mean ± SD	Male Range	Female Mean ± SD	Female Range	p-value
Mass (g)	680 ± 39	640–730	775 ± 25	750–800	0.006
SVL (cm)	29.4 ± 1.6	27.1–31.4	31.4 ± 0.8	30.5–31.8	0.053
Total Length (cm)	64.9 ± 3.4	59.5–68.5	67.9 ± 1.3	66.5–69.1	0.125

Habitat use and diet was similar to that reported for wild skinks from other islands in the archipelago (Honegger 1975; McCoy 2000; Parker 1983). The skinks were found in large rainforest trees, with strangler figs (*Ficus* sp.) a preferred species (McCoy 2000). The trees always had extensive surrounding vines, especially *Scinadapsus* sp. and *Piper* sp. (Honegger 1975; Parker 1983). All skinks except one were found during the day inside holes in large trees in primary rainforest. The exception was a male found foraging in a tree among *Scinadapsus* vines on an overcast day. No individuals were found on the ground at any time, and lizards were frequently found high in the trees (4–9 m above ground). Stomach contents of a dissected female included a large amount of partially digested leaf matter, along with the red fruit of the *Scinadapsus* vine, previously identified as a preferred food of *C. zebrata* (Parker 1983). The stomach also contained large numbers of small parasitic nematodes, as reported previously (Iverson 1982). No insect matter or skin fragments were seen in the digestive tract of either dissected lizard.

Skinks observed for this study showed a range of coloration similar to that described previously (Köhler 1997; McCoy 2000; Schmidt 1991), but also possessed a unique sexual dichromatism. Three individuals had scattered entirely or partly black scales along the body, although the number of these markings varied greatly between individuals. Adults range in color from olive green to dark green, some with very distinct lighter stripes along the sides of the body and others with no apparent stripes. Both juveniles were olive green in color with distinct stripes. The skinks also showed variation in eye color, with the iris varying from yellow-green to dark brown. The darkest eye color was observed in the three adult females. All five of the adult male skinks had a distinctive yellow patch on the underside of their throat, a feature lacking in adult females. Balsai (1995) stated that males can often be distinguished by wider jowls and large, broad heads. Sexual dichromatism, however, has not been described for other populations of *Corucia zebrata*, and may be unique to this population. Previous authors have reported other examples of inter-island variation in *C. zebrata*, with several studies showing differences in coloration between skinks from Malaita and Bougainville (McCoy 1980; Schmidt 1991). McCoy (1980) stated that skinks from Malaita are darker than those from elsewhere in the Solomons. Schmidt (1991) reported that animals from Malaita tend to have yellow coloring at the front of the head, which was sometimes present along with the throat patch in male skinks captured on Isabel. Also, Schmidt (1991) suggests that there is more variation in the prominence of stripes among skinks from Bougainville, and this variation also seems to be true for skinks from Isabel. Kohler (1997) identifies differences in iris color and head color as distinguishing characters between the Bougainville species (*C. zebrata alfredschmidti*) and the Solomons subspecies (*C. zebrata zebrata*). However, my examination of Isabel specimens in the field shows wide variation in both of these color patterns, with individuals from the same population exhibiting a range of body and eye colors representative of both subspecies. Further characterization of geographic variation in *C. zebrata* will require more data collected from individuals throughout the archipelago. In particular, previous work has focused on skinks from Bougainville and Malaita, but including material from Isabel, located between these two islands, could give a more complete picture of geographic variation in the species.

I also verified previous reports (Honegger 1975; Kinghorn 1928; Parker 1983) of skinks using communal holes as resting places during the day. Of the twelve lizards caught, 8 (67%) were found sharing tree holes with conspecifics. These groups included three pairs, two of which were adult male-female pairs. One pair member, a gravid female, was eaten by a local family before data could be collected, while the second female, caught in October 1999, was dissected (see below) and found to be gravid with a well-developed embryo. A third pair consisted of an adult female with a juvenile. A group of three was also found, consisting of an adult male, an adult female, and a juvenile (the larger of the two juveniles found). This group was found in a tree hole that contained standing water. The bottom two lizards were completely submerged, with the male's head raised just above the water. The female in this group, caught and dissected in late May 2000, had a number of small, yolkless eggs in her abdomen, but no obvious developing embryos. Previous studies have reported groups of skinks in a single hole, with the skinks resting in the bottom of holes being much thinner, and surviving off the feces of those above (Kinghorn 1928). No evidence was found for this, and such stories seem to be absent from local folklore on Isabel. Observations of skinks sharing holes suggest that they might have stable social aggregations, as seen in *Egernia stokesii* (Gardner et al. 2001), likely a close relative of *C. zebrata* (Honda et al. 1999). Further research using paternity analysis could be used to test the hypothesis of stable aggregations and family structure in these skinks.

I made observations of reproduction of *Corucia zebrata* in the wild that corroborate observations from captive animals. In captivity, the skinks usually give birth to a single large offspring (Honegger 1975, 1985), although twins have been reported (Hediger 1937; Honegger 1985; Schmidt 1991). I found a single large, membrane-covered yolk mass (~9 x 7 x 5 cm) and embryo (~5 cm SVL) in one female that was dissected. The total mass of yolk and embryo was 140 g, representing a relative clutch mass of 0.19, which is within the range of values found for other skinks (Vitt and Price 1982).

This dissection also provided an opportunity to investigate autotomy in prenatal *Corucia zebrata*. I used forceps to apply a slight tug to the tail of the embryo, and it immediately broke in the center leaving a jagged edge. The force required to break the tail was

extremely small, and seemed to be much less than the force needed to tear through normal embryonic tissue of that thickness. Adult *C. zebrata* do not exhibit autotomy, perhaps as a consequence of their unique tail morphology (Zippel et al. 1999). Furthermore, newborn *C. zebrata* also are unable to lose their tail. Other species in the *Mabuya* group, which includes *Corucia* (Greer 1989), lose the ability to autotomize during ontogeny (Cogger 1975). The embryo's brittle tail suggests that *C. zebrata* might also show this ontogenetic shift, a possibility suggested by Arnold (1984).

Although the status of this species in the wild is unknown, these skinks are likely threatened by both the international pet trade and by local consumption (Balsai 1995; Honegger 1975). *Corucia zebrata* remains a sought-after food item in the Solomons (Hediger 1937), especially in rural areas on Isabel and other islands. Solomon Islanders frequently seek out this species during nighttime hunts, and their pungent smell makes them easy targets for experienced hunters. Such hunters can find multiple individuals in a single night, and report success rates of more than 10 per night in some locations. The Solomon Islands has the fastest rate of population growth in the Pacific (Population Reference Bureau 2000), and this species is under constant and increasing threat from human hunters. Furthermore, they have suffered from over-collection for the international pet trade. Records show increasing trade in *C. zebrata*, both in the US and internationally, during the early 1990s (Hoover 1998). Over 12,000 *C. zebrata* were imported into the US alone in the period 1992-1995 (Hoover 1998). They remain a popular species in the pet trade. Because of lack of field studies of these lizards in their natural habitat, their present status is uncertain, and the effects of consumption and the pet trade on their populations are unknown. More studies are needed to understand and protect these unique lizards.

Acknowledgments.—I thank the students and staff of Sir Dudley Tuti College, Kamaosi, Ysabel, for assistance in collecting and measuring lizards. L. L. Harmon aided in collecting and recording data. R. Glor, J. Kolbe, and J. Losos provided helpful suggestions during the preparation of this manuscript, as did R. Honegger, B. Hollingsworth, and two anonymous reviewers.

e-mail: Lrichter@ou.edu

Understanding larval biology is of interest because of continuing concerns about declining amphibian populations (Alford and Richards 1999). Various studies have documented the effects of anthropogenic stressors to larval anurans using field enclosures (e.g., Semlitsch et al. 2000), though most authors do not describe enclosure design (see Harris and Bogart 1997). To address the effects of chemicals associated with landfill leachate on development of gray treefrog (*Hyla versicolor*) tadpoles in the field, we constructed enclosures for rearing larvae to monitor survival and

body condition through metamorphosis (S. Richter, unpubl. data).

The enclosures allowed a large number of larvae to be reared at moderate and equal density (one larva per liter; up to 60 larvae per enclosure) by monitoring the number of larvae per enclosure and adjusting depth (thus volume) of the enclosure accordingly. They were designed to remain in the water column and stationary with respect to location in the pond and could be moved vertically as water levels changed between and within study ponds. The top was securely attached but could easily be removed to allow multiple sampling. Our design is an alternative to larger field pens (e.g., Wilbur 1976), which must be placed on the pond bottom and moved horizontally if water levels change. Both methods are valid; the appropriate enclosure should be chosen based on goals and logistics of the study.

Each enclosure was cylindrical and housed in an outer cage, which allowed the inner enclosure to be removed when necessary (Fig. 1). The cylinder of the inner enclosure was constructed of 1.6-mm aluminum screening (92 cm high and 30.5 cm diameter), and the top and bottom panels were made from 1.6-mm fiberglass screening and attached to the cylinder using 30.5-cm cross-stitch hoops, which are readily available at craft stores. To ensure proper size, we wrapped the aluminum screen around the inner hoop of the 30.5-cm wooden cross-stitch hoop (made of two hoops, the outer with a screw for tightening material between them), stitched the seam closed using 20-gauge galvanized wire, and then sealed the seam using nontoxic silicon. We attached the top and bottom panels with the cross-stitch hoops. The inner hoop was stitched to the inside of the cylinder with 20-gauge galvanized wire. A 35.5-cm^2 piece of fiberglass screening was placed over the hoop and cylinder; then the outer hoop was positioned over the screen and tightened with the screw. Thus, the cylinder and end screen were tightened between the inner and outer hoops. We strengthened the bottom by applying nontoxic silicon around the edges of the outer and inner hoop and cutting away excess fiberglass screening. No silicon was applied to the top of the enclosure so that it could be removed to sample larvae and metamorphs.

The outer cage was a cylinder with an open top made of 1.3-cm, 19-gauge hardware cloth and was slightly larger (2.5 cm) in diameter and 2/3 the height of the inner enclosure. We stitched the bottom panel (33 cm diameter) to the cylinder (61 cm high) using 20-gauge galvanized wire. We attached the outer cage to a stake in the study pond using two wood screws and plastic cable ties, which allowed depth to be adjusted by cutting the cable ties, placing the cage at the new level on the wood screws, and replacing the cable ties. The outer cage protected the inner cage from floating debris and ensured that it maintained an upright position. It was adjusted as water levels changed within and between sites to maintain an equal water volume in the inner enclosure. When installed with the top 10 cm above the water surface, the volume of water in the inner enclosure was 60 L (total volume = 67 L).

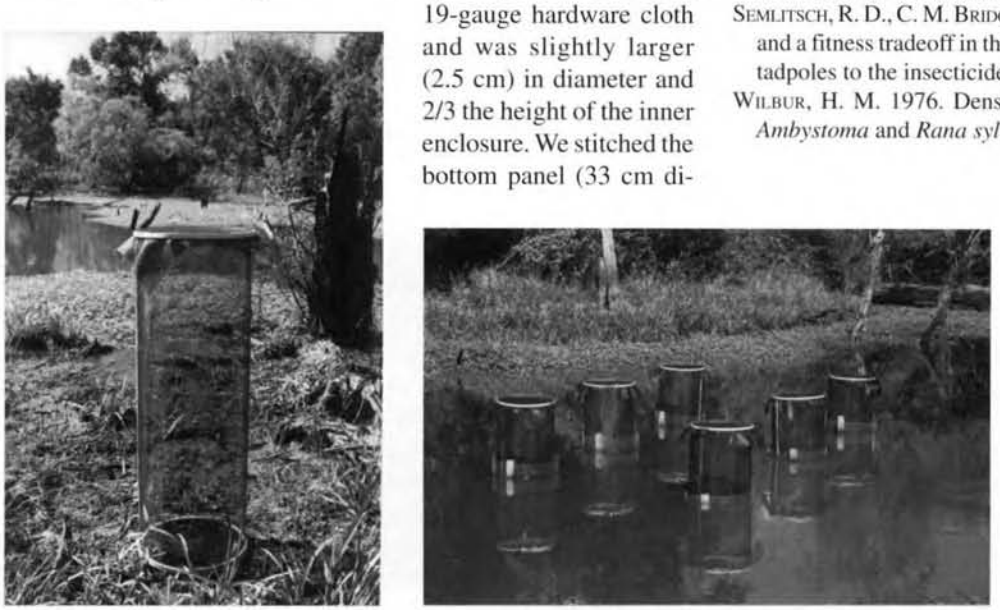

FIG. 1. Field enclosure showing (left) inner component and (right) inner components installed in outer components in the field.

Because of the small size of most early-stage anurans compared to the mesh of the inner enclosure, eggs and embryos might need to be housed in the laboratory in water from the study ponds until the larvae reach a large enough size to preclude escape. If the experiment needs to begin in ponds, our enclosure could be modified by replacing the fiberglass and aluminum screening with Nitex nylon (500-µm mesh; Tetko, Inc., New York), as used by Harris and Bogart (1997).

Our method can be used in various studies of larval amphibians. The two-component design (outer cage and inner enclosure) is unique and allows multiple sampling through metamorphosis while maintaining equal water volume between sites with ease. The large size allows high initial density of larvae so that multiple sampling is possible with adequate sample sizes. The enclosure is particularly useful in studies designed to assess the effects of different pond environments on various stages of anuran development or in studies that manipulate density as a treatment.

Acknowledgments.—We thank Janalee P. Caldwell for comments on the manuscript.

Activity and movement patterns of animals are fundamental issues in many areas of biology, particularly ecology and conservation biology. Locomotor activity patterns in squamate reptiles under controlled laboratory situations concurrent with some physiological measure (e.g., aerobic capacities) is well studied compared to other reptilian groups, particularly freshwater turtles (reviewed by Garland and Losos 1994). For lizards, the standard device for measuring locomotor performance has long been the treadmill or a variant thereof (Beck et al. 1995; Carpenter and Ferguson 1977). This simple device has endless functional (e.g., sprint speed) or ecophysiological (e.g., effects of temperature on locomotion) application. One reason for the lack of similar studies involving freshwater turtles is the lack of an apparatus for measuring basic aspects of locomotor activity. While there are many studies that measure the movement and activity of freshwater turtles in the wild (e.g., Bodie and Semlitsch 2000; Brown and Brooks 1993; Morreale et al. 1984; Rowe and Moll 1991), we are aware of only three studies that investigate proximate questions of locomotion and activity under controlled laboratory conditions in freshwater turtles (Brett 1971; Cash and Holberton 1999; Finkler 1998). Here we describe an apparatus that we designed for quantifying locomotor activity in freshwater turtles. We also provide suggestions that expand the applicability of our device.

Activity chambers were constructed from 75 L opaque plastic tubs (heavy-duty, solid walled laundry basket: 50 cm diameter top, 42 cm diameter bottom, 41.5 cm depth; Fig. 1). At the bottom of each tub, a plastic tray platform (40 cm diameter, 4 cm depth) was placed atop a stationary point; a golf ball (~ 4 cm diameter) adhered to the bottom-center of the tub with Dap waterproof silicone, which allowed the platform to pivot. A small hole (1.5 cm diameter) was drilled in the center of the platform (the point at which the platform rested on the pivot ball) to help stabilize the platter on the ball. Four to six non-slip bathtub adhesive strips (approx. 1.5 cm diameter) were attached to the platform to provide traction for the turtle. The platform was suspended with strands of 20-gauge wire, distributed equally around its perimeter, from the lever of each of the four micro-switches (Omron Industries model # B2-2RW80-82) distributed equally around the top of the tub. The micro-switches on each tub were mounted to the inside of the tub using two small metal bolts (standard #6 x 2 in.). Each of the four micro-switches was wired to the power supply and to a common ground in sequence such that when a lever was depressed on any switch an electrical circuit was completed and registered (see Fig. 2) on the single Sodeco digital counter (2.5W, 12V DC)

FIG. 1. Illustration showing a side cut-away of the locomotor activity apparatus with golf ball, platform, turtle and one micro-switch shown (50 cm diameter top, 42 cm diameter bottom, 41.5 cm depth).

mounted on each tub. In this way, any movement by the turtle on any part of the platter, regardless of its direction, would result in a count on the counter. Each activity apparatus was then connected to a single Epsco DC variable power supply (0–16V, 0–10 Amp). The amount of volts provided could be adjusted for the number of turtles to be monitored. Power could be supplied continuously or be turned on and off automatically by a plug-in timer. Turtles were placed in their respective activity apparatus chamber and the water level was adjusted based on the size of the turtle (to the top of the turtle's carapace). Regardless of the turtle's direction of movement, the platform would be displaced, thus depressing one or more switch levers. A variety of measurements can be made from these data (e.g., counts per hour, counts over a 24 h period), depending on the scope of the investigation.

Other considerations warranted attention. In studies involving the slider turtle, *Trachemys scripta* (Cash and Holberton 1999; Cash, unpubl. data), turtles were found to elicit what could be described as "escape behavior" within the first 24 h after being placed in the activity chambers. Activity levels are often significantly higher than any mean activity level after the initial 24 h. Therefore, it might be important to include an acclimation period, which might be species specific, before activity recording begins. The water level was checked daily in order to insure that the recording dynamics of each apparatus remains constant over the duration of the activity trials. It was also important to insure that each chamber received equal light intensity, which ideally, should be homogeneous within the chamber. Finally, there might be variation in turtle body mass and size, as well as sensitivity in platform movement to turtle activity, that could potentially obfuscate differences in treatments of interest (for instance, the mass range for turtles used in the study by Cash and Holberton (1999) was 404.1 to 1280.0 g). We recommend that, for comparisons across treatment groups, variation in turtle mass or size be equally distributed

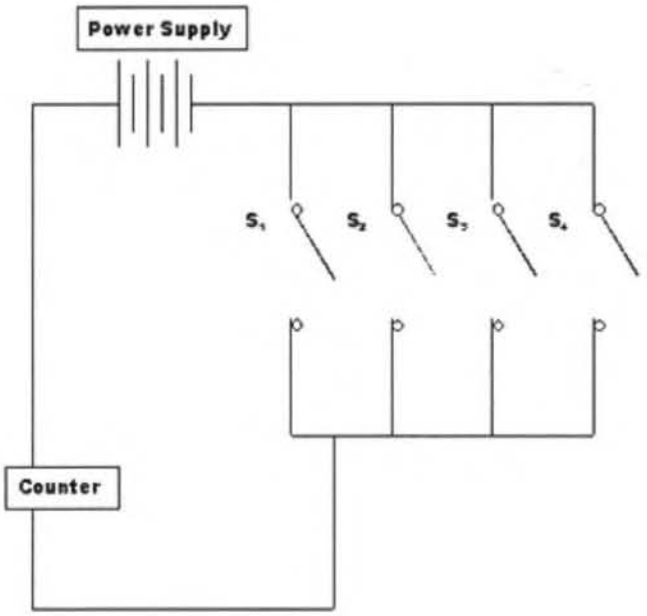

FIG. 2. A schematic of the basic locomotor activity circuit. S1 – S4 represent each micro-switch.

across the groups of interest. When looking for changes in activity within individuals, we recommend that the same turtle be maintained in its original chamber throughout the study (cf. Cash and Holberton 1999).

There are additional applications that the activity chambers provide, with modification. The simple addition of voltage specific resistors in the line to all micro-switches would enable each of these points to have unique voltage. By using a logging digital multi-meter with a serial interface or similar device (analog/digital board; computer interface; Vernier Serial Logger Pro), the capabilities of the activity chambers greatly expands. This modification first allows temporal recording of activity data that would enhance the experimental design options and hence the number and different types of questions that the investigator could ask. Questions related to circadian biology could be explored. Because each micro-switch can have a unique voltage requirement (with resistors in-line), these points could be assigned and oriented to directional coordinates (i.e., N, S, E, W) for use in studies regarding orientation, water finding, and homing ability in freshwater turtles.

We believe that the locomotor activity apparatus provides a simple way of quantifying locomotor activity in freshwater turtles. The devices lend themselves to comparative studies where investigators are interested in basic locomotor activity and the effects of specific independent variables (e.g., hormone application, Cash and Holberton 1999) on this activity. The devices are not, however, intended to measure other aspects of locomotor performance, like endurance or sprint speed. Except for the DC variable power supply, which costs ca. US $270 but can be used to power multiple chambers, each chamber can be constructed for ca. US $35 from material that can be purchased at a local hardware store. We believe that the activity apparatus provides an inexpensive, easy-to-construct way to enhance our understanding of the behavioral ecology and physiological ecology of a poorly understood group of animals, under controlled laboratory conditions.

Acknowledgments.—We thank Jill King for the expert drawing of Fig. 1 and Terry Bunde for help with the schematic shown in Fig. 2.

Among the many techniques that have been used to study amphibians, funnel traps are commonly recommended to determine species presence, breeding success, and relative abundance of amphibian larvae in aquatic habitats. Several authors have discussed the advantages and disadvantages of funnel traps for sampling amphibian larvae (Adams et al. 1997; Fronzuto and Verrell 2000; Shaffer et al. 1994). However, recent reviews of methods for studying amphibians (Heyer et al. 1994; Olson et al. 1997) make it clear that more research is needed on the species-specific

effectiveness of methods that have been proposed.

A variety of funnel traps have been tried and tested including commercially available cylindrical traps constructed of 6 mm mesh galvanized wire, box funnel traps made of 3 mm mesh galvanized wire (Mushet et al. 1997), traps made from plastic beverage bottles (Calef 1973; Griffiths 1985; Richter 1995), collapsible nylon mesh traps (Adams et al. 1997), and traps constructed with acrylic plastic sheet (Smith and Rettig 1996). Some authors have compared the effectiveness of funnel traps of different styles and materials. Smith and Rettig (1996) compared the efficacy of three homemade funnel traps constructed of PVC pipe, acrylic plastic sheet, and plastic beverage bottles. Mushet et al. (1997) compared the effectiveness of cylindrical 6 mm mesh galvanized wire traps to their 3 mm mesh galvanized wire box traps. Fronzuto and Verrell (2000) compared the efficacy of cylindrical 6 mm mesh galvanized wire and cylindrical 2–4 mm mesh plastic funnel traps. Our objectives were to: 1) determine the efficacy of commercially available funnel traps for catching aquatic amphibian larvae living in small seasonal forest ponds, and 2) determine if net leads would enhance the efficacy of funnel traps.

We conducted the study on a selection of seasonal forest ponds in northern Minnesota on the Sucker Lakes Watershed in Cass County and on the Rice River Watershed in Itasca County. In 1997, we compared capture rates of commercially available plastic versus metal funnel traps and investigated the effect of adding net leads. The plastic funnel trap [Nylon Net Company, Memphis, Tennessee; MT1 at US $6.90 each in orders of six or more] consisted of two halves fastened in the middle of the trap; one half was colored blue and the other white. Dimensions of this near cylindrical trap were 43.2 cm long, 22.9 cm maximum diameter, and a 2.4 cm entrance centered in an 11.4 cm deep funnel positioned on each end of the trap. Mesh size of the plastic trap ranged from 4 x 6 mm where the trap halves join, to 3 x 4 mm at the trap ends. The metal funnel trap [Cuba Specialty Manufacturing Co., Fillmore, New York; G-40 at US $7.80 each] also consisted of two halves clipped together in the middle of the trap. Its dimensions were very similar to the plastic trap, only its length was slightly shorter (41.9 cm) and the dimension of its entrance was variable (2.2–2.4 cm). Metal traps were constructed of galvanized hardware cloth, which had larger openings (four holes per 2.5 cm, or 6 x 6 mm mesh size) than those of the plastic traps.

In 1997, we trapped amphibians in 29 ponds for three consecutive days each, from 18 June through 7 August. Metal and plastic traps were paired side-by-side in shallow water perpendicular to shore in water deep enough to submerge the trap entrance, yet still provide air for amphibians to breathe. Three trap pairs were spaced roughly 3–6 m apart along the shore in each pond, regardless of pond size. A net lead was positioned between the plastic and metal traps of the central pair. The net lead consisted of a 3.0 m long minnow seine staked from a position located between the traps out into deeper water. Traps were not baited and were set out during the day on Mondays, checked daily the following three days, and removed on the last day. Captured amphibians were identified to species, counted, and released.

In 1998, we trapped amphibians in 45 ponds for three consecutive days each, from 3 through 25 June, to compare capture rates of metal funnel traps of two different mesh sizes; 4 openings per 2.5 cm (6 x 6 mm mesh) and eight openings per 2.5 cm (3 x 3 mm mesh). Traps with 3 mm mesh were substantially more expensive than traps with 6 mm mesh [Cuba Specialty Manufacturing Co., Fillmore, New York; US $19.53 (G-48M) versus US $7.80 (G-40).] Traps were not paired as in 1997 but instead, were evenly spaced around the pond, alternating mesh sizes from a random start. We set 2 to 6 traps (1 to 3 traps of each mesh size) in ponds; the number of traps chosen so as to approximate an equivalent effort per unit of pond surface area. As in 1997, unbaited traps were set out Monday, checked the following three days, and removed. Captures were handled as in 1997.

Data were first converted from counts of larvae in each trap over the three trap night period to a daily capture rate for each trap and species (total number of individuals captured for a species divided by three trap nights). Repeated measures ANOVA was used to determine if 1997 daily capture rates of three species differed between trap types (plastic versus metal) and between trap pairs with net leads versus those on either side that lacked net leads. These analyses were conducted using square root transfor-

TABLE 1. Descriptive statistics for analysis of the efficacy of two funnel trap types (plastic versus 6 mm mesh, metal hardware cloth) and efficacy of net leads for capturing amphibian larvae of three species. Number of traps, median capture rate (CR) [number of individuals captured per night in each trap, averaged over three trap nights], and interquartile ranges are reported. N = number of ponds where species was trapped out of 29 possible ponds.

Species	Statistic	All Plastic	All Metal	Plastic Net	Plastic Without Net	Metal Net	Metal Without Net
Rana sylvatica	Number of traps	66	66	22	44	22	44
N = 21	Median CR	0.67	0.83	0.33	0.67	1.17	0.67
	Interquartile range	0.00, 1.33	0.33, 2.67	0.00, 1.33	0.00, 1.50	0.33, 2.67	0.33, 3.67
Ambystoma laterale	Number of traps	42	42	14	28	14	28
N = 14	Median CR	0.33	0.00	0.17	0.33	0.00	0.00
	Interquartile range	0.00, 1.00	0.00, 0.33	0.00, 1.00	0.00, 0.83	0.00, 0.33	0.00, 0.33
Pseudacris crucifer	Number of traps	12	12	4	8	4	8
N = 4	Median CR	0.00	0.00	0.00	0.00	0.00	0.00
	Interquartile range	0.00, 1.17	0.00, 0.00	0.00, 0.17	0.00, 2.00	0.00, 0.33	0.00, 0.00

mations to normalize the data. Data for 1998 were summarized as a daily capture rate for each trap type (6 mm versus 3 mm mesh) in a pond. Wilcoxon signed ranks tests were used to determine if 1998 daily capture rates differed between the two trap mesh sizes for three species (the simplified 1998 experimental design allowed use of this test and avoided assumptions about normality of data). All analyses were conducted using SYSTAT 8.0.

TABLE 2. Analysis of the efficacy of funnel traps constructed with hardware cloth of two different mesh sizes (6 mm versus 3 mm openings) for capturing amphibian larvae. For each species, a capture rate per night was calculated for each trap type in each pond by averaging the total number of larvae captured for each trap type in each pond (N = 1 to 3 traps per pond) over a 3-day period. Tests of significance were derived from a Wilcoxon signed ranks test.

Species	Statistics	6 mm Mesh	3 mm Mesh	Z	P
Rana sylvatica [Present in 35 ponds]	No. ponds where captured	33	35	-1.028	0.304
	Median pond capture rate	4.1	3.8		
	Interquartile range	0.9–24.2	0.9–16.4		
Ambystoma laterale [Present in 15 ponds]	No. ponds where captured	2	15	3.308	0.001
	Median pond capture rate	0.0	0.3		
	Interquartile range	0.0–0.0	0.2–0.9		
Pseudacris crucifer [Present in 15 ponds]	No. ponds where captured	5	14	3.023	0.003
	Median pond capture rate	0.0	0.3		
	Interquartile range	0.0–0.2	0.2–1.1		

In 1997, wood frog (*Rana sylvatica*) larvae were captured in the most ponds, followed by blue-spotted salamanders (*Ambystoma laterale*), and spring peepers (*Pseudacris crucifer*) (Table 1). The median daily capture rate of wood frog larvae in metal traps was 0.83 per trap compared to 0.67 in plastic traps, whereas median daily capture rates of blue-spotted salamander and spring peeper larvae were lower than those of wood frog larvae in either type of trap (Table 1). Trap type was a significant variable in explaining daily capture rates of wood frog ($F_{1,20} = 13.92$, $P < 0.001$), but not blue-spotted salamander or spring peeper larvae ($P > 0.20$ for both species). Neither net leads ($P > 0.55$ for all species) nor an interaction of net leads and trap type ($P > 0.30$ for all species) affected daily capture rates of any species.

In 1998, wood frog larvae were again captured in the most ponds (35 ponds), whereas blue-spotted salamander and spring peeper larvae were found in 15 ponds each (Table 2). Traps with 3 mm mesh correctly recorded species occurrences in all but one instance (3 mm mesh traps failed to record spring peepers in one pond). In contrast, 6 mm mesh traps did a poor job in recording the presence of species with small larvae (i.e., blue-spotted salamander and spring peeper). Median daily capture rates of wood frog larvae were slightly higher in 6 mm than in 3 mm mesh traps, but not significantly so ($P = 0.30$). In contrast, daily capture rates of spring peeper and blue-spotted salamander larvae were greater ($P < 0.005$) in traps constructed with 3 mm versus 6 mm mesh hardware cloth.

Funnel traps of many styles and materials have been used by investigators to sample amphibians in aquatic settings. It is clear from their collective experiences that several factors impinge on the efficacy of funnel traps in capturing amphibians. For example, effectiveness is known to vary by species, trap characteristics, size of larvae, and habitat conditions (Adams et al. 1997; Fronzuto and Verrell 2000; Shaffer et al. 1994). Our results support these findings with regard to species, trap characteristics, and size of larvae.

Trap characteristics had a significant effect on capture rates of amphibian species found in our small, seasonal forest ponds. Our 1997 results demonstrated that 6 mm mesh metal traps were more effective than plastic traps in capturing wood frog tadpoles. We did not determine why this was so; e.g., we do not know if the plastic trap's blue and white color or physical appearance lowered wood frog capture rates. In contrast, plastic traps had slightly higher capture rates of blue-spotted salamanders than metal traps. Although this difference was not statistically significant, it makes sense that the smaller mesh size of plastic traps would reduce the likelihood of the smaller salamander larvae escaping from these traps. These observations were consistent with Fronzuto and Verrell (2000) who reported that some long-toed salamanders (*Ambystoma macrodactylum columbianum*) escaped from metal funnel traps with 6 mm mesh size, but not from plastic funnel traps that had a smaller mesh size.

In 1998, we confirmed the importance of mesh size. Metal traps with 3 mm mesh were better at capturing species with small larvae (i.e., blue-spotted salamander and spring peeper) than traps with 6 mm mesh openings. At the same time, captures of larger wood frog larvae in 3 mm versus 6 mm mesh traps were similar. These results suggest that 6 mm mesh hardware cloth might not adequately sample small larvae. We conclude 3 mm mesh funnel traps would provide a more unbiased assessment of the relative abundance of amphibian larvae living in our seasonal forest ponds.

Net leads, drift fences, and drive nets have been used to enhance capture of a variety of fish (Hubert 1983) and wildlife (Day et al. 1980) species, including herps in terrestrial settings (Heyer et al. 1994). These devices intercept the movement of animals and direct their travel towards traps. Because net leads are very effective in fisheries surveys, we thought they might also enhance the efficacy of unbaited funnel traps in catching amphibian larvae. Our result that they were not effective in directing amphibians into traps was surprising and is worthy of further study. The larvae of some amphibians school or diurnally migrate in response to light, temperature, and oxygen concentrations (Duellman and Trueb 1986). Perhaps amphibian species that live in small forest ponds are more sedentary than these amphibians or fishes, and thus their capture is less likely to be affected by net leads.

In summary, of the funnel traps we tested, we recommend using metal traps constructed of 3 mm mesh hardware cloth for sampling amphibian species whose larvae or adults are small, or when assessing the relative abundance of species in communities that include species with such characteristics. If one is sampling only species with large larvae or adults, 6 mm mesh might be adequate

or possibly preferable. Net leads did not enhance capture rates of larvae of the amphibian species we encountered in small forest ponds, perhaps because their larvae are relatively sedentary. The same might not be true for larvae of other amphibians, especially those that live in larger aquatic habitat types. This possibility has implications for amphibian methodology, sampling design, and understanding of larval behavior. We suggest that these be explored further to understand the mechanisms underlying our results using net leads.

Acknowledgments.—We thank Jim Church and Mike Becker who assisted with data collection and Dave Rugg whom we consulted in the course of analyzing the data. We also thank Gary Casper, Julie Fronzuto, Mike Lannoo, Sharyn Marks, John Moriarty, and Klaus Richter who provided valuable comments on earlier drafts of the manuscript. Mention of trade names or companies does not constitute endorsement of their products by the USDA Forest Service.

The brown treesnake, *Boiga irregularis*, was inadvertently introduced from Australasia to Guam around the end of World War II (Savidge 1987). By the mid 1980s brown treesnakes were abundant and distributed island-wide (Rodda et al. 1992; Savidge 1987). The snake irruption is believed responsible for the extirpation of nine of the island's 13 native forest bird species (Savidge 1987), loss of two lizard species (Fritts 1988), and for a drastic decline in numbers of the Mariana fruit bat, *Pteropus m. mariannus* (Wiles 1987). Additionally, brown treesnakes caused more than 1650 electrical outages on Guam between 1978 and 1997 (Fritts and Chiszar 1999; T. H. Fritts, unpubl. data).

Currently, brown treesnake control efforts are divided into two areas: reducing snake abundance in localized areas of Guam, and preventing dispersal of snakes from Guam. One dispersal-prevention tool used on Guam, Oahu (Hawaii) and Saipan (Northern Mariana Islands, NMI) is the detector dog program (Engeman et al 1998a; Engeman et al. 1998b; Vice and Engeman 2000). Detector dogs are trained to recognize the scent of brown treesnakes that have stowed away in cargo, and to signal the presence of the snakes to their handlers. Initial training of the dogs and ongoing refresher training requires frequent exposure of the dogs to live brown treesnakes. This poses no problem on Guam where snakes are plentiful. However, importation of brown treesnakes to Hawaii and the NMI for dog training is problematic. Recently, the export to Hawaii of a limited number of sterilized male brown treesnakes for dog training has been approved (importation of live females and reproductively intact males is not permitted). Unfortunately, there is no established protocol for sterilizing male snakes. Thus, we identified a need for a simple and immediately effective method of sterilizing male brown treesnakes for export to snake-free areas for training snake detector dogs.

Thirty male *Boiga irregularis* were collected from the wild on Guam. Each snake's snout–vent length (SVL), total length (TL), and mass were recorded prior to it being individually housed in a plastic box (34 x 24 x 13 cm) with numerous ventilation holes. Each box contained a lining of white paper, a water dish, and a piece of PVC pipe in which the snake could shelter. The room in which the snakes were housed was ventilated by air from outside the building. All snakes were offered one dead adult mouse weekly from the time of capture until the termination of the experiment. Of the 30 candidate snakes, 29 settled into captivity and fed at every weekly feeding session. These 29 snakes were retained for

use in the experiment. At the conclusion of the experiment 25 of the snakes were euthanized. The "working life" of a sterilized brown treesnake is likely to be on the order of a few months. Therefore, we retained four snakes in captivity for observation to determine if there were any longer-term effects of the experimental procedure on the snakes.

Each snake was assigned to one of three experimental treatments: both hemipenes removed by ligation; one hemipenis removed by ligation (either left or right); or no hemipenes ligated (control treatment). The initial size of snakes did not differ among experimental treatments (1 factor ANOVA, initial mass: $F_{2,26}$ = 0.54, P = 0.591, initial SVL: $F_{2,26}$ = 1.09, P = 0.351). All snakes increased in mass over the course of the study (mean increase in mass = 28%, range = 14–48%). There was no difference among treatments in the daily rate of mass increase (1 factor ANOVA, $F_{2,26}$ = 1.16, P = 0.331).

Two people were required to carry out each ligation procedure. One person restrained the snake and everted the target hemipenis by applying thumb pressure to the base of the snake's tail. A second person swabbed the hemipenis and cloacal area with Brite-Life® 2% iodine tincture (Bergen Brunswig Drug Company, California) and sprayed the area with Lanacaine® anaesthetic spray (benzocaine 20%, benzethonium chloride 0.2%; COMBE, Inc., White Plains, New York). The second person then placed a hemostat clamp transversely across the everted hemipenis midway down its length to prevent its withdrawal back into the snake. At this point, pressure on the tail base was released. A modified transfixation technique using a C-23 cutting needle with a non-absorbable suture attached (Bralon®, 3-0 braided nylon; USSC sutures) was used to ligate the hemipenis. The needle and suture were passed through the base of hemipenis, then looped around the hemipenis and secured in place with a square knot. The suture was tightly wrapped around the hemipenis a second time and secured with another square knot. An option at this stage of the procedure would be to sever the hemipenis distal to the ligation site to ensure that the structure is successfully removed. However, we did not do this. Consequently we have no data on infection rates, recovery times, or mortality of snakes that have had their hemipenes severed. After completion of the ligation procedure, the hemostat was removed and the snake was returned to its holding box. Between 10 and 15 minutes were required to complete each bilateral ligation. This included the time required to capture the snake from its holding cage, complete the procedure, and return the snake to its holding cage.

Between four and six weeks post-procedure we conducted a blind assessment of the success of the ligations. A combination of techniques (attempted eversion of hemipenes and internal probing of hemipenes) was used to determine whether each hemipenis was intact or the tissue fused at the point of ligation. Skilled application of pressure to the base of a brown treesnake's tail will generally evert an intact hemipenis. However, if this method fails to induce eversion, a blunt-ended probe can be inserted gently into the hemipenis lumen. In an adult male brown treesnake with intact hemipenes, the probe will pass 25–30 mm into the lumen before reaching the end of the inverted hemipenis. In a snake that has undergone the ligation procedure there are three possible outcomes:

1) If the procedure has been successful, and the wound has healed over, the probe will not enter beyond the point of ligation (typically 2–4 mm deep).

2) If the procedure has been successful but the ligation site has not healed over and sealed completely, the probe will pass through the unhealed wound to a depth considerably greater than the usual 25–30 mm.

3) If the procedure failed, the probe will enter to a depth of around 25–35 mm.

For each snake the evaluator used both eversion and probing techniques to score the presence or absence of hemipenes.

The blind evaluation procedure correctly assigned every snake to its experimental treatment. That is, correct assessment (as ligated or not ligated) of all 58 hemipenes was achieved. Of the 33 ligations (bilateral in 12 snakes and unilateral in nine snakes), 32 were completely successful: the portion of the hemipenis distal to the suture was gone, and the base of the hemipenis was fully healed over. One ligated hemipenis remained partially intact (ca. 10 mm of hemipenis remained). It is very unlikely that this hemipenis was functional as the wound at the distal end of the hemipenis was completely healed over, thus preventing the passing of fluids (including semen).

To compare the ability for ligated versus intact hemipenes to pass ejaculatory fluid we attempted to collect fluids from each snake. Fluid collection was achieved by massaging the base of each snake's tail at the time of the evaluation. Successful collection of any fluid implies that the posterior section of the sperm duct contains the fluid and that there is no blockage preventing passage of the fluid from the sperm duct. An unsuccessful collection attempt means that either fluid is not present in the posterior section of the sperm duct, or that it is present but it is prevented from moving because of a blockage in the sperm duct, or that the method used to collect the fluid has failed. Thus, collection of any fluid is conclusive evidence that the sperm transfer mechanism is potentially still intact, but unsuccessful collection attempts are inconclusive.

Fluid was successfully collected from 16 (64%) of the 25 intact hemipenes, whereas none (0%) of the 33 ligated hemipenes could be induced to pass any fluid. The probability that failure to collect fluid from all 33 of the ligated hemipenes was because of chance is extremely low ($P < 0.0001$, $\chi^2 = 29.2$, 1 d.f.). Thus, the ligation treatment successfully prevents fluids (including ejaculate) from leaving the snakes.

Five months after ligation of both of their hemipenes, the four snakes that were held for observation remained healthy and were feeding well. There were no signs of hemipenis regeneration and no fluid could be forced from any of the eight ligated hemipenes.

We have termed this sterilization technique the "bilateral hemipenis ligation" method. Each sperm duct is ligated at its most posterior point. Thus, there is no reservoir of viable sperm left posterior to the ligation site. Additionally, the intromittent organs are removed, thereby curtailing the ability to copulate. There are some species with internal fertilization that mate without benefit of a male intromittent organ (e.g., most birds, tuatara), however these species have evolved to convey sperm without the aid of such structures. Female brown treesnakes have not so evolved, so sperm transfer by hemipenis-ligated males should be very appreciably hindered.

Our method of sterilizing male brown treesnakes is effective

(successful in at least 32 of 33 attempts), quick (the procedure requires less than fifteen minutes per snake) and inexpensive (less than US $1.00 per snake for materials). The technique has a 0% mortality rate in laboratory tests, and it requires only a moderate skill level. Failed attempts are very easy to identify; if a hemipenis is still present, it can be detected via manual eversion or probing. Thus, there is very little risk of exporting a non-sterile snake from Guam. We recommend that bilateral hemipenis ligation of male snakes is adopted by agencies that need an increased supply of sterile snakes for training detector dogs in areas at risk of brown treesnake infestation.

Acknowledgments.—We thank Dan Vice of USDA-APHIS-Wildlife Services for his discussion of current brown treesnake sterilization techniques and for helpful comments on this manuscript. We also thank Dr Joseph Edlund for allowing us to observe him castrating a brown treesnake. Wendy Chen and Jason Hackman provided excellent technical assistance and maintained the snakes throughout this study. Kathy Dean-Bradley, Gordon Rodda, Julie Savidge, and Diane Vice provided valuable comments on the manuscript. All research was conducted with the consent of the Ohio State University Institutional Laboratory Animal Care and Use Committee (protocol approval numbers 96A0137, 97A0064, 97A0141, 97A0142).

Snout-to-vent length (SVL) is a standard measure of the body size of salamanders, but the vent of an eastern red-backed salamander (*Plethodon cinereus*) can be difficult to see under adverse conditions and on small individuals. The legs, however, are obvious. Regression analysis showed that SVL can be predicted from snout-to-hind-leg length (SLL) with a high degree of accuracy. The regression model was validated with an independent *P. cinereus* data set which suggested that, within the species, it has wider applicability than the data set from which it was derived. Compared with SVL, SLL is relatively easy to measure resulting in more rapid processing of salamanders, less stress to the animals, and has potential for use even by inexperienced observers in a large monitoring program.

The eastern red-backed salamander (*Plethodon cinereus)* may be common in the woodlands of southeastern Canada and northeastern portions of the United States. Wyman and Hawksley-Lescault (1987) noted sensitivity of these salamanders to changes in soil pH, and Frisbie and Wyman (1995) concluded that the species is a potentially useful sentinel of change within forest ecosystems. *Plethodon cinereus* has been selected as an indicator of the sustainability of forest management practices in Ontario (McLaren et al. 1998). Measures of body length could provide valuable information for a variety of questions related to environmental impact and habitat use (see above), as well as behavioral interactions and interspecific competition (e.g., Jaeger 1972).

Petranka (1998) described standard measures of body size for salamanders as total length and snout-to-vent length. Total length (TL) is measured from the tip of the snout to the tip of the tail on a straightened body. Snout-to-vent length (SVL) is usually measured from the tip of the snout to the posterior margin of the vent (though sometimes the anterior margin of the vent has been used). Compared with TL, SVL is a more reliable measure of body length for *Plethodon cinereus* because these salamanders regularly autotomize their tails if threatened. Also, tails are frequently bitten

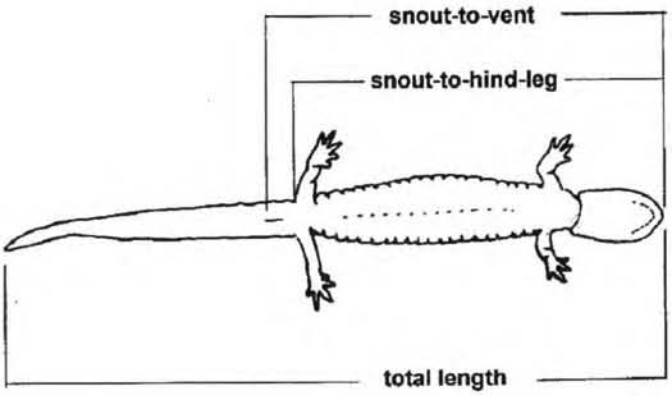

FIG. 1. Ventral view of a *Plethodon cinereus* illustrating how total length (TL), snout-to-vent length (SVL), and snout-to-hind-leg length (SLL) were measured on live specimens. SLL is measured on a straightened animal from the tip of the snout to the posterior surface of a hind leg where it joins the body.

during agonistic interactions (Jaeger et al. 1982), and this might result in breakage (Petranka 1998). However, *P. cinereus* are small, with adults typically ranging from 65 to 125 mm in total length, and hatchlings from 19 to 25 mm (Petranka 1998). Vents can be difficult to see, particularly on juveniles, and on all ages at night when these salamanders are most readily observed and captured.

In this paper we use regression analysis to relate standard SVL to snout-to-hind-leg length (SLL), a new measure of body length which is more easily assessed on small animals under sub-optimal conditions. Like SVL, SLL is affected less than TL by agonistic interactions and predation.

The study was conducted in central Ontario, within a radius of approximately 40 km to the east and south of the city of North Bay (approx. 46°13'N, 79°22'W). It was part of a larger project designed to compare sampling techniques (see Hackett et al. 1999; Szuba 1999). Two sets of data were used in the analysis: the main data set to derive a regression equation, and an independent data set to test it. Data used for derivation were collected from two sites: a mature sugar maple (*Acer saccharum*) stand and a mature white pine *(Pinus strobus)* stand. Test data were obtained from 36 different sites that were spread out over the larger study area. The 36 test sites were mature forest stands representing three main vegetation types: a) mixed poplar (*Populus* spp.), white birch (*Betula papyrifera*), and balsam fir (*Abies balsamea*), b) mixed sugar maple, white birch, poplar, and white pine, and c) sugar maple mixed with yellow birch (*B. alleghaniensis*).

A variety of techniques was used to locate salamanders, including cover boards (76 x 20 x 2.5 cm in size) that were checked during the day or night, diurnal searches in 1 m^2 litter plots, diurnal searches under or inside natural cover objects in 25 m^2 quadrats, and above-ground searches along prescribed transects at night.

Plethodon cinereus were captured periodically on all study sites from late April to mid-October 1998. Each salamander was placed in a thin plastic bag and held in such a way that the animal was immobilized in a relaxed position. SVL, SLL, and TL were measured on the ventral surface of the straightened body (Fig. 1) to the nearest millimeter with the aid of a ruler. If the precise location of the distal end of the vent was indeterminable in the field, we did not measure SVL and data for that animal were excluded from the SVL analysis. Thus, the analysis includes measures only for those animals whose vents were clearly visible, presumably reflecting an accurate assessment of SVL. We also noted condition of the tail (intact, or with obvious signs of breakage or regrowth). We did not differentiate between the sexes or among ages.

Linear regression analysis was used to determine the relationships among body measurements (Analytical Software 2000). Data from the two main sites were used as input (N = 363) to build the model relating SVL and SLL. A Durbin-Watson test was performed on the residuals from this analysis to check for autocorrelation (independence of residuals; Analytical Software 2000). Residual plots were also examined visually to determine if the residuals were normally distributed and homoscedastisic. The regression model was validated using two approaches. First, the test data (N = 214) were run through the regression model to determine the number of cases that fell outside the 95% prediction interval. A prediction interval is expected to contain observed values of the dependent variable 95% of the time (Analytical Software 2000). Second, a new regression analysis was performed in which actual measurements from the test batch were used as the dependent variable, and the predicted values for the same salamanders were used as the independent variable. If the test data fit the equation well, there should have been a non-significant intercept, and the slope of the regression line should not have differed significantly from 1.0 (Montgomery and Peck 1982). A high R-square would also indicate a good fit.

Linear regression of SLL and SVL resulted in a highly significant model (F = 5010.9, df = 362, P = 0.000) that fit the data well (R^2 = 0.933; Fig. 2). There was no significant autocorrelation among residuals (Durbin-Watson statistic = 1.9809, P of positive correlation = 0.4244, P of negative correlation = 0.5756, N = 363). Residual plots also suggested that the residuals were normally distributed and homoscedastisic. The regression of SLL and TL also was significant (F = 1077.84, df = 362, P = 0.031). However, TL was not predicted as well from SLL (R^2 = 0.748; Fig. 3). This was expected, and probably reflects a combination of phenotypic variation in tail lengths, and the results of injury or autotomization (and

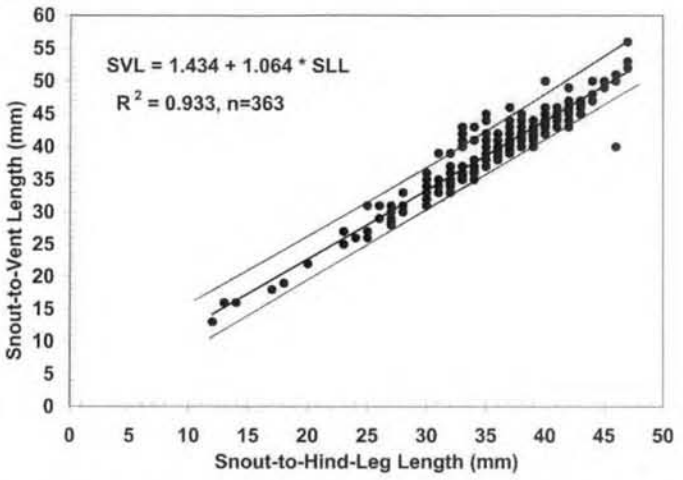

FIG. 2. Linear regression model relating snout-to-hind-leg length (SLL) and snout-to-vent length (SVL) of *Plethodon cinereus* captured near North Bay, Ontario. The solid lines show the 95% prediction interval (PI) for SVL. True (or observed) values of SVL are expected to fall within the PI 95% of the time.

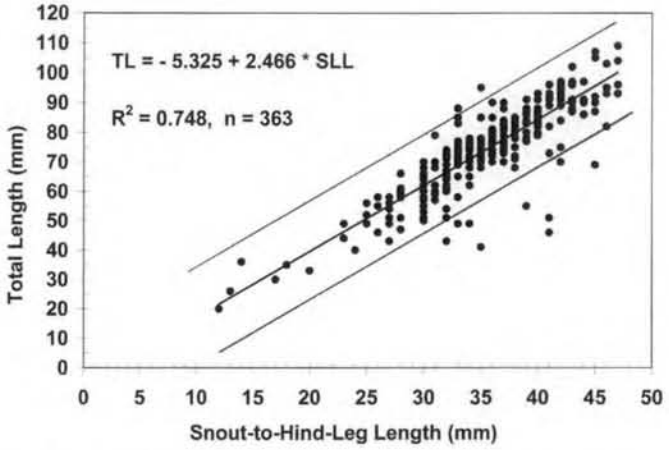

FIG. 3. Linear regression model relating snout-to-hind-leg length (SLL) and total body length (TL) of *P. cinereus* captured near North Bay, Ontario. The solid lines show the 95% prediction interval for TL. True (or observed) values of TL are expected to fall within the PI 95% of the time.

subsequent regrowth) that were not caused by the sampling methods. Seventy-nine (21.8%) of the *P. cinereus* used to derive the regression equation showed obvious evidence of past tail damage or regrowth (e.g., discontinuity of the tail profile manifested as an extremely blunted tip, an extremely pointed tip beyond an old injury, or, in a few cases, most of the tail missing).

Validation of the SLL/SVL model with the test data suggested that the model has wider applicability for *Plethodon cinereus* than the data base from which it was derived. When the test data from the larger area were run through the regression model, only 5 of the 214 values (2.3%) fell outside the 95% prediction interval. Moreover, performing a new regression of actual SVLs from the test data and predicted SVLs from the model resulted in a highly significant regression ($F = 4872.82$, $df = 213$, $P = 0.000$) with a non-significant intercept ($P = 0.9777$), a slope not significantly different from one ($t = 0.708$, $df = 212$, $P = 0.478$), and a high R-square value ($R^2 = 0.958$). Thus, both of these tests failed to invalidate the SLL/SVL model.

In the field, SLL was relatively easy to measure under a variety of conditions. The ease of measurement resulted in more rapid processing of individuals and therefore less handling and associated stress to the study animals. Legs were much more obvious on the smaller individuals than vents. This gives SLL the potential to be measured easily and accurately by unskilled volunteers participating in salamander monitoring programs.

Future research could involve testing or calibrating this equation in other parts of the geographic range of *Plethodon cinereus*. Alternately, SVL could be predicted for other populations using a two-phase sampling scheme. This would involve measuring SLL on all salamanders, and SVL on a subset to develop a regression estimator for the local area. A regression of SLL and SVL might also prove to be useful for other species of small salamanders.

Acknowledgments.—Nina Barbetta, Naomi Barratt, Tammy Lott, Tanya Ingwersen, and Jennifer Todd were enthusiastic and able field assistants. Andree Morneault and Dianne Othmer also helped to collect data. Dave Harding provided logistic advice in Samuel de Champlain Provincial Park. Howard Stauffer and Jason Lowe provided helpful comments and suggestions as part of the peer review process. Financial and logistic support were generously supplied by Nipissing University and the Wildlife Assessment Unit of the Ontario Ministry of Natural Resources. We sincerely appreciate these contributions.

The use of general anesthetics is the standard procedure for the implantation of radiotransmitters in snakes (Anderson et al. 2000; Reinert 1992; Reinert and Cundall 1982; Weatherhead and Anderka 1984; and see excellent reviews by Hardy and Greene 1999, 2000). However, the use of general anesthesia presents several limitations, which are compounded in the field. If an injectable general anesthetic is used, investigators must become proficient in finding veins (usually the tail vein) or in heart puncture (Anderson et

al. 2000). If an inhalant general anesthetic is used, the investigator must be able to regulate the amount of anesthetic given, and experience is needed to reduce overdosage and the use of artificial ventilation for resuscitation (Hardy and Greene 2000). The use of any general anesthestic necessitates the determination of safe dosages for a given species and the possibility of death because of overdosage. This report shows that a local anesthestic can be used safely and effectively in the field for the implantation of radiotransmitters. The use of local anesthesia virtually eliminates the possibility of death because of overdosage and simplifies the surgical procedure without compromising the health of subjects. In addition, recovery times are significantly shortened, and snakes can be released safely within 4 h post-surgery.

We have begun studies on the spatial ecology of *Boa constrictor imperator* on Ometepe Island, Nicaragua, in order to examine similarities and differences with temperate snakes for orientation. Ometepe is an island of 276 km^2 in Lake Nicaragua. By studying the spatial ecology of boa constrictors on Ometepe, we hope to identify preferred habitat and movement patterns and understand the thermal ecology of these snakes. Four *Boa constrictor imperator* were purchased from local residents, and the exact location and time of capture were noted. All snakes were captured in the municipalities of San Ramon and La Tijeretas on the south to southeast sides of the volcano Maderas. All snakes inhabitated secondary growth, dry tropical forest interspersed with agricultural fields.

Radiotransmitters were surgically implanted between 11 and 17 July 2000. Before surgery, all snakes were weighed, measured, sexed, and all external ticks were removed. We used two males and two females (N = 4), ranging from 153 to 171 cm snout–vent length and 1.9–3.4 kg. Snakes were implanted with temperature-sensitive radiotransmitters (151–152 MHz, G3-Temp B [CS1 and CS2] or SM1-H-Temp B [CS3 and CS4], AVM Instrument Co., Livermore, California, USA), which were less than 2% of body weight. Transmitters and instruments were soaked in 100% ethanol for 10 min and then rinsed in 0.9% sterile saline prior to implantation. All surgeries were performed using aspetic technique.

Snake heads were covered with cotton socks to reduce visual stimuli to the snake as well as to prevent bites to investigators (Rivas et al. 1995). The sock was secured with a rubber band around the neck. The upper third of each snake was placed in PVC tubing (tubing technique of Murphy 1971), and the remainder of the snake was restrained by 2–3 people. The operating table was first wiped with Betadine (10% povidone-iodine solution) and then covered with a sterile cloth. The snake's ventral scales were exposed, wiped with Betadine, and a total of 1.5 ml of 2% lidocaine hydrochloride without epinephrine (Astra Pharmaceuticals, Westborough, Massachusetts, USA) was injected subcutaneously and intramuscularly as a local anesthetic underneath three, consecutive ventral scales approximately 40 cm anterior to the cloaca. For any snake, this would be equivalent to a total dosage of 0.5 ml of lidocaine/kg of snake given approximately one quarter of the snake's length anterior from the cloaca. Injections were made using a sterile 1 ml tuberculin syringe with a 3/8 inch, 26 gauge needle. Investigators holding snake near incision site and making incision wore sterile gloves. After 10 min without physical restraint, the snake was restrained again; the injected region was poked with a 26 gauge needle to ensure the absence of a withdrawal reflex; and a transverse incision (approx. 4 cm) was made with a sterile scalpel underneath the middle of the three ventral scales injected previously with lidocaine. A radiotransmitter was inserted into the peritoneal cavity and advanced posteriorly with a sterile cotton applicator, leaving the end of the whip antenna underneath the incision site (Fig. 1). No reflexive or excessive movements were noted during intraperitoneal implantation. The incision was then closed with 3-0 Dexon II absorbable suture (Davis-Geck Inc., Manati, Puerto Rico, USA) in a subcuticular, simple interrupted, horizontal pattern so that skin edges and dermal layers are everted and closely opposed for strong healing (Hardy and Greene 1999). The sutured incision is then covered with liquid bandage (New Skin, Medtech Laboratories, Inc., Jackson, Wyoming, USA) in order to provide additional strength. The entire procedure from the injection of lidocaine to placement of the last suture ranged from 20 to 30 min (recall that 10 of those minutes are waiting for the lidocaine to take effect). Snakes were allowed to recover for 3 to 10 h. The tops of their heads were painted with green latex paint (Wash 'n Wear, Glidden Co., Cleveland, Ohio, USA), and they were released at their capture points.

Snakes were tracked once or twice daily over 22–30 days and localized 14–25 times, using a TRX-1000S receiver and 3 element folding Yagi antenna (Wildlife Materials, Inc., Carbondale, Illinois, USA). At the end of this period, three of the four snakes

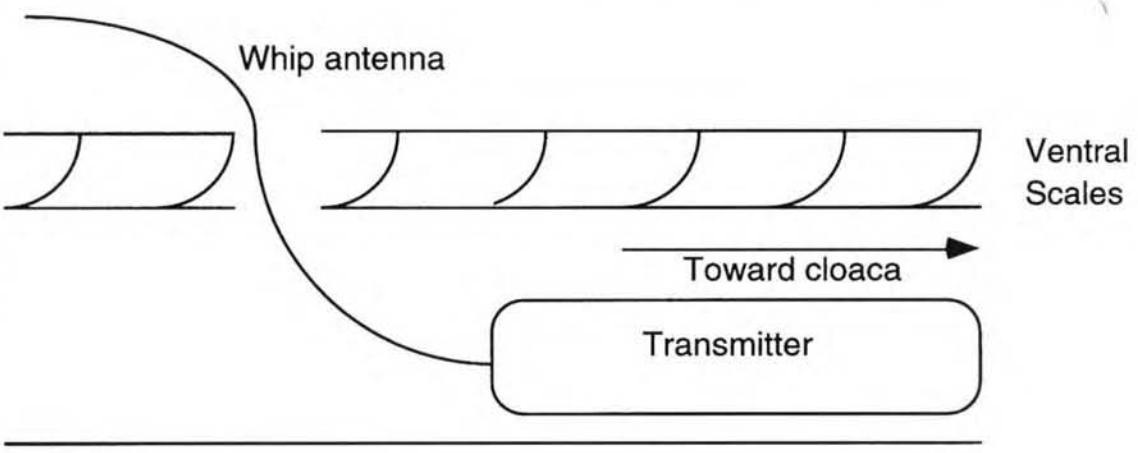

FIG. 1. Placement of radiotransmitter in body cavity. Snakes were injected with a total dosage of 0.5 ml of lidocaine/kg of snake (distributed under three consecutive ventral scales), given approximately one quarter of the snake's length anterior from the cloaca. A transverse incision was made with a sterile scalpel underneath the middle of the three ventral scales injected 10 min previously with lidocaine. After the transmitter is pushed caudally, the antenna lies completely within the body cavity. All surgeries were performed using aspetic technique (see text for details).

were recaptured, and transmitters were removed using the same procedures described above. After injection of lidocaine, transmitters were removed by an incision at the same incision site made for implantation, followed by closure as described above. In all cases, no movement of the transmitter had occurred, and all transmitters were removed by gently palpating the transmitter anteriorly. No adverse effects were seen on snakes released within 3 h of surgery, and no signs of infection or necrosis were observed at the time of transmitter removal. Indeed, one snake had no signs of surgery except for a faint line between the reattached ventral scales.

Although we have only attempted this technique on four animals in the field to date (and two corn snakes, *Elaphe g. guttata*, at the Seneca Park Zoo prior to field work), the surgery technique described has several advantages over those described previously. First, there is virtually no chance of mortality because of anesthesia. This is critical when working with species that are rare or hard to obtain, working with gravid females, or when working under primitive conditions. Although this method necessitates physical restraint, we feel that the slight discomfort and stress experienced by the subject for less than 20 min is minimal compared to the risk of mortality using general anesthesia. In addition, the injection of lidocaine affords adequate analgesia at the surgical site, does not necessitate any special training, and can be performed safely using sterile syringes and needles. The implantation of radiotransmitters and antennas into the body cavity did not harm the snake in any way and did not affect the transmission of signals. We were able to localize snakes in thick, secondary forest up to 150 m (the greatest distance traveled by an individual between localizations). Although this method could potentially be used with any species, it might be advisable to use general anesthesia when working with venomous species to minimize the chance of envenomation.

Acknowledgments.—Our research was supported by NSF grant IBN No. 9904572 to DAH and a grant to CDS from the Ophidian Research Colony. We thank the Ometepe Field Station for use of facilities, Rodolfo Ruíz for help with tracking and handling boas, and D. Hardy, Sr., N. Ford, and R. Sajdak for helpful comments and suggestions. All procedures were approved by the Seneca Park Zoo Animal Care and Use Committee.

While recent refinement of miniaturized radiotransmitters has made it possible to study small organisms using radiotelemetry (White and Garrott 1990), determining how to attach transmitters to small animals is still problematic. Anurans might be particularly difficult to attach transmitters to because of the sensitivity of their skin. Transmitters attached externally might get caught on objects in the environment and cause abrasions. Implanting transmitters requires the researcher to conduct surgery, a longer process that leaves an incision which might become infected. In this paper, we compare the effectiveness of internal and external radiotelemetry attachment methods for a terrestrial anuran, the barking frog (*Eleutherodactylus augusti*), and provide details on implantation of transmitters.

Many materials have been used to attach external transmitters to anurans: beaded metal chain (Rathbun and Murphey 1996; Matthews and Pope 1999), latex (Van Nuland and Claus 1981), rubber (Fukuyama et al. 1988; Werner 1991), satin ribbon (Bull 2000), webbing (Schwarzkopf and Alford 1996), gauze bandages (Hodgkison and Hero 2001), and silicone (Holenweg and Reyer 2000), polyethylene (Bartelt and Peterson 2000), and teflon tubing (Waye 2001). Many of these attachments have resulted in sores and limited mobility of frogs, perhaps leading to decreased survivorship (Bartelt and Peterson 2000; Bull 2000; Rathbun and Murphey 1996; Waye 2001; Werner 1991; P. Griffen, pers. comm.). Common frogs (*Rana temporaria*) and common toads (*Bufo bufo*) force-fed transmitters regurgitated them in 2–38 days (Fiorito et al. 1996; Oldham and Swan 1992).

For longer studies, some researchers (Richards et al. 1994; Werner 1991) have suggested that implanting the transmitter into the coelomic cavity might be less dangerous to the frog than attaching it externally. Most published field studies using implantation in anurans do not discuss any effects of transmitter implantation (Bradford 1984; Carey 1978; Denton and Beebee 1993; McClanahan and Shoemaker 1987; Seitz et al. 1992; Smits 1984; Stinner et al. 1994), but some report no infection or direct mortal-

ity (Eggert et al. 1999; Lamoureux and Madison 1999; Olders et al. 1985; Sinsch 1988; Speiler and Linsenmair 1998). One study noted infection in one of six individuals implanted, apparently because of improper suturing (Werner 1991). Implanted transmitters did not negatively affect survival, feeding, or weight change in salamanders (*Ambystoma maculatum*) in field and laboratory experiments (Madison 1997).

We used three methods to attach radiotransmitters (models BD-2T [external, 1.55 g], BD-2HT [internal, 1.4–1.45 g], BD-2G [external, 1.2–1.4 g], BD-2GH [internal, 1.25–1.55 g]; Holohil Systems Ltd., Carp, Ontario, Canada) to barking frogs in the Huachuca Mountains of southern Arizona during the summers of 1996, 1999, and 2000. Transmitters were built to last 9 weeks. In 1996 we used aluminum beaded chain belts (Rathbun and Murphey 1996) on four frogs and in 1999 we surgically implanted transmitters in six frogs. In 2000 we surgically implanted transmitters in five frogs and used a silicon tubing belt (P. Griffen, pers. comm.) on one additional frog. This belt was made of a silicon tube (2.1 mm outside diameter; Cole-Parmer Instrument Co., Vernon Hills, Illinois, USA) which had 10-pound test fishing braid (SpiderWire, Pure Fishing, Spirit Lake, Iowa, USA) at the core and tied in a knot. We pushed the knot back into the tube and glued the ends together with a drop of silicon glue, fitting the belt as described in Bartelt and Peterson (2000). This external belt was on a gravid female; we avoided operating on gravid females because of possible complications with the egg mass. Implanted transmitters had helical antennae; external transmitters had whip antennae. Mass of transmitters did not exceed 5% of the mass of the frog. Transmitters were 15 or 16 mm in length; frogs had snout–vent lengths between 67 and 81 mm and masses between 25 and 45 g.

To anesthetize frogs for implantation surgery, we used an aqueous solution of 0.03–0.05% tricaine methanesulfonate (MS-222, Finquel, Argent Chemical Laboratories, Inc., Redmond, Washington, USA) buffered with sodium bicarbonate to pH 7 as recommended by Fellers et al. (1994). The depth of the solution was shallow enough to enable the frog to sit on the bottom of the container and have its mouth above water. We conducted surgeries on large, autoclaved sponges to soak up any solution that ran off the frog when anesthetic was administered during the surgery by pipette or soaked gauze. We avoided getting solution in the incision.

Transmitters were coated by the manufacturer with a non-reactive coating of butyl rubber and we had them gas sterilized prior to surgery. We autoclaved all surgical instruments and used sterile gloves for each surgery. We made a 12–15 mm incision laterally with a #11 scalpel blade and used Polysorb 6/0 suture with a tapered, half-circle needle (United States Surgical Corporation [USSC], Norwalk, Connecticut, USA) to close the peritoneal tissue. This tissue was very thin, and we used two or three simple, interrupted sutures to close this layer. We used Monosof 5/0 (USSC) suture with a 3/8 circle reverse cutting needle and closed the skin with seven or eight horizontal mattress sutures. Using a mattress stitch ensured that inner epidermal layers were opposed, creating an area of rapid healing that reduced the chance of infection.

We attempted to dose the frogs with the appropriate amount of anesthetic so that they started to recover during skin closure, indicating that we had not over-anesthetized them. After surgery, we placed frogs in very shallow water and changed it regularly until they were alert. We then replaced the water with a damp paper towel. We usually conducted surgeries in the morning and released frogs that same night.

In 1996, one frog lost its beaded chain belt after five days. Sores were not seen on the other three frogs two weeks after attachment but the frogs developed bleeding ulcerations on their sides by 21 days in the field. In 2000, the frog with the silicon belt did not have sores after 11 days in the field. She remained almost completely underground for the next 34 days, when we observed that she had deep ulcerations on both sides and immediately removed the belt. Signals from transmitters attached externally were audible from greater than 200 m.

We conducted 11 implantation and 7 transmitter removal surgeries. One removal procedure was not successful because the frog came out of anesthesia before we retrieved the transmitter and did not respond to additional anesthetic; we closed the incision and released the frog with the transmitter still implanted. One transmitter that we successfully removed had moved out of the coelomic cavity to a subcutaneous position, probably because of an inadequate number of sutures in the peritoneal tissue. No irritation or wearing of the skin was apparent from the transmitter being in this position, and the peritoneal tissue had healed completely. We did not attempt to retrieve transmitters from the remaining four frogs: two frogs entered their overwintering sites with transmitters still implanted, one frog stopped moving in the second week of radiotelemetry and presumably died of unknown causes, and one frog prolapsed its bladder after surgery. We drained the bladder of this frog and moved it back inside the body cavity as we released the frog. This frog moved in a similar pattern to other frogs throughout the season, but we decided that recapturing it for transmitter removal would be more stressful to the frog than leaving the transmitter implanted.

Frogs usually took between 10 and 20 minutes to reach a surgical level of anesthesia, but this was highly variable (range 6–45 min). When a frog did not right itself when placed on its back, we determined that it had reached the appropriate level of anesthesia and removed it from the solution. We found that waiting for the toe pinch reflex to disappear (Fowler 1993; Van Gelder and Bugter 1987) resulted in a dangerously deep level of anesthesia. One frog that was allowed to reach this level was unconscious for more than two hours and eventually had to be revived by tracheal intubation and ventilation with oxygen. Barking frogs often did not breathe for several minutes at a time during surgery, but their heartbeats were visible. Occasional pharyngeal breathing indicated an appropriate level of anesthesia. We often had to continue to administer anesthetic solution to frogs during the surgery.

Immediately after coming out of anesthesia, many frogs resumed a defensive posture by filling their lungs with air to increase their size and some males started calling immediately upon release. The skin of all frogs that we observed had healed completely within two weeks of the surgery. We observed a slight thickening of the lung tissue in one frog that had a transmitter inside it for over a year, but no inflammation was apparent. All other removal surgeries were conducted 5–9 weeks after implantation. We saw no evidence of infection or mortality due to implantation of transmitters; we recaptured 7 of the 10 frogs one year after surgery and saw no external evidence of the surgery aside from a barely visible scar. Signals from implanted transmitters were audible from a maximum distance of between 6 and 40 m.

Both methods of external attachment of transmitters to barking frogs caused potentially dangerous ulcerations. Even though our sample size is small, we feel that the consistency of our results is important to note. Terrestrial species such as barking frogs might be especially prone to developing sores from dirt trapped under belts and harnesses because of the lack of water to wash away abrasives. In addition, it is often impossible to inspect visually the effects of belts and harnesses on frogs that occupy underground areas.

Achieving the appropriate level of anesthesia was the most problematic part of surgery. Similar concentrations of MS-222 have been used in studies of *Rana arvalis* (0.05%; Van Gelder and Bugter 1987), *Rana temporaria* (0.02–0.03%; Seitz et al. 1992), *Bufo calamita* (0.05%; Sinsch 1988), and *Bufo bufo* (0.02%; Olders et al. 1985). Other studies have successfully used much higher concentrations for *Rana muscosa* (0.4%; Bradford 1984) and *Rana clamitans* (0.5%; Lamoureux and Madison 1999), and lower concentrations for *Bufo americanus* (0.01%; Werner 1991). The higher concentrations would almost certainly have caused mortality in barking frogs, while the lower concentration would likely have resulted in too shallow a depth of anesthesia.

With careful use of anesthesia and sterile protocols, we believe that implantation of transmitters is the safest and most reliable method of transmitter attachment for terrestrial anurans if the length of the study is sufficient to allow for healing. Aquatic frogs might be less prone to injury from belts and more easily accessed for examination, and external attachment might be a more appropriate method for them. The short distance at which the transmitter signal is audible might also limit the use of this method with more mobile species.

While we hope that the information provided in this paper will enable field biologists to safely implant transmitters in frogs, we emphasize that surgery is a difficult and risky undertaking for any species. Researchers should only operate on sensitive species after they have practiced techniques on other frogs (we used bullfrogs [*Rana catesbeiana*] from an extirpation program), preferably under the supervision of an experienced surgeon.

Acknowledgments.—Funding for this project was provided by the Arizona Game and Fish Heritage Program, National Park Service, and Southern Parks and Monuments Association. Barbara Alberti of the National Park Service initiated this study and contributed with field, administrative, and editorial work. We would like to thank Brenda Carbajal and Cecily Westphal for administrative assistance, Erika Duross, Cori Dolan, Mary Gilbert, and all our volunteers for fieldwork, and Don Swann, Dale Turner, and two reviewers for their helpful comments. Surgeries for this project were conducted under IACUC #99-038.

A Historical Study of the Distribution of Blanchard's Cricket Frog (*Acris crepitans blanchardi*) in Southeastern Michigan

RICHARD M. LEHTINEN
University of Michigan Museum of Zoology
Division of Reptiles and Amphibians, 1109 Geddes Avenue
Ann Arbor, Michigan 48109-1079, USA
e-mail: rmlehtin@umich.edu

"We have seen it from New Jersey to Georgia, Louisiana, Texas and Iowa, but like most workers we have neglected this most ubiquitous tree frog. Everyone remarks their choruses." (Wright and Wright 1949)

Unfortunately, Wright and Wright's (1949) characterization of the abundance of *Acris crepitans* is no longer accurate. In recent years, there have been numerous reports of declines in populations of Blanchard's cricket frog (*Acris crepitans blanchardi*), particularly in the midwestern US and adjacent Canada (e.g., Minnesota [Oldfield and Moriarty 1994]; Wisconsin [Hay 1998; Mossman et al. 1998]; Iowa [Hemesath 1998; Lannoo et al. 1994]; northern Illinois [Mierzwa 1998]; northern Indiana [Brodman and Killmurry 1998]; Ontario [Oldham 1992]). Frost (1983) and Hammerson and Livo (1999) have also reported declines from the western edge of its range.

In Michigan, Blanchard's cricket frog was historically widely distributed in the southern half of the lower peninsula (Harding 1997; Ruthven et al. 1912). Isolated records also exist for populations in the northern portion on the lower peninsula (Lee 1998; Ruthven et al. 1912). However, there has been no recent, published report of the current distribution of these frogs in Michigan. Surveys by the Michigan Department of Natural Resources and data from the Michigan Frog and Toad Survey indicate that this species is still somewhat abundant in southwestern Michigan, but is rare in the southeastern part of the state (Lee 1998).

Long-term monitoring of distribution and abundance is critical to the ability to detect and respond to declines (Pechmann and Wilbur 1994). Museum specimens, when accompanied with appropriate locality data, provide unequivocal evidence of the occurrence of a species at a certain time and place. These, and other records, provide us with information on the historic distribution of a species and can be used in conjunction with contemporary surveys to assess its current distribution and conservation status (Shaffer et al. 1998).

To assess the historic distribution of Blanchard's cricket frog in southeastern Michigan, I compiled a database of historic localities for this species in 14 counties in southeastern Michigan, USA. This database was based on records from museums, the scientific literature, the Michigan Natural Features Inventory, the Michigan Frog and Toad Survey, and reports from local naturalists. I limited my search for historical information to the following counties in southeastern Michigan: Genesee, Hillsdale, Ingham, Jackson, Lapeer, Lenawee, Livingston, Macomb, Monroe, Oakland, Shiawassee, St. Clair, Washtenaw and Wayne. A total of 79 historic localities were found in the study area dating from 1878 to 1999. These historic localities included three habitat types: lakes (35%), ponds (39%) and rivers or streams (26%).

A difficulty in conducting historical studies is that the quality of information varies greatly, particularly in older records. For example, many specimens or literature records simply refer to a township or a city, (e.g., "Norvell Township" or "Ann Arbor") without any specific locality data. Also, some older records use long forgotten names (e.g., "Steere's marsh" or "Fiegel's woods"). Some of these were located after consulting old maps, but others had to be excluded from further consideration. In all, 60 localities were sufficiently informative that they could be relocated and surveyed.

Chorusing surveys were conducted at these 60 sites for Blanchard's cricket frogs during the peak breeding season. At each site, after a five minute acclimation period, I listened ten minutes for vocalizations of male cricket frogs. If cricket frogs were detected, I attempted to collect a reference specimen. Chorusing surveys were conducted between 2000 and 0100 h. The minimum air temperature to conduct a chorusing survey for cricket frogs was

FIG. 1. Location of sixty historical localities (1878–1999) for *Acris crepitans blanchardi* in fourteen counties in southeastern Michigan, USA. Open circles represent extinct populations, shaded circles represent extant populations, based on 2001 surveys.

effectively at the site following disturbance. In order to document revegetation of the site, we also measured changes in the biomass of plant material over time. Although the rate of increase slowed in 1999 (1.05 m^3/month) compared to 1998 (1.52 m^3/month), the total biomass of vegetation at the site continued to grow throughout the study period.

Public education is key to the success of any conservation program. Thanks to a supplemental award from the National Science Foundation's Informal Education Program, we have been able to incorporate a public education component into our work on the base. Although Cuban iguanas comprise a conspicuous component of the local fauna and have been adopted as an informal mascot by many base residents, their biology and conservation status are not widely understood or appreciated. A major focus of our educational efforts has been to provide opportunities for the general public to participate actively in our field research effort. On three separate trips in 1997, we offered interested volunteers on the base the opportunity to participate in standardized iguana censusing and help collect data on antipredator and thermoregulatory behavior. Feedback from over 40 participants in the form of surveys was overwhelmingly positive, with 93% of respondents finding the research experience extremely worthwhile, 83% of respondents experiencing a positive shift in attitude regarding scientific research following their field experience, and 90% of respondents indicating that they would recommend the research experience to other base residents.

In collaboration with HVS Productions, we also produced a video that describes the basic biology of iguanas, their conservation status and requirements, and the goals, study methods, and results of our research program. Copies of the videotape have been distributed to the environmental office, library, and schools on the base. On each of our trips to the base, we have offered public lectures at which we provide information on iguanas, their conservation status, and how to appreciate and enjoy them without harming them. We have given numerous presentations to both elementary and secondary students on the base, prepared an endangered species pamphlet for incoming base personnel, and designed an Iguana Crossing sign for sites on the base where road casualties were known to have occurred.

Our work at Guantanamo Bay is but one example of the many contributions zoos are making to the conservation of West Indian iguanas. Over 20 American Zoo and Aquarium Association (AZA) member institutions have provided direct funding and other resources to West Indian iguana conservation projects, primarily in Jamaica, but also in Dominica, the Cayman Islands, the Dominican Republic, the Bahamas, the Turks and Caicos Islands, and the British Virgin Islands. With the help of zoos and other dedicated conservation partners, some of the rarest and most impressive lizards in the world are starting to make a comeback.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 33, Number 1 (March 2002).

GYMNOPHIONA

OSCAECILIA ZWEIFELI (Zweifel's Caecilian). **PREDATION**. Virtually nothing is known about the ecology of *Oscaecilia zweifeli* (Lescure and Marty 2000. Atlas des Amphibiens de Guyane. Patrimoines Naturels, 45). At the field station of Nouragues (4°5'N, 52°41'W 110 m elev.), 8 km N of Saut Pararé, Arataye River, French Guiana, during the rainy season on 25 May 1999, one of us (RB) found, under a rotted trunk on the ground, an *O. zweifeli* (Museúm National d'Histoire Naturelle, Paris [MNHN] 1997.6482) whose head was maintained by the chelicera of an adult giant tarantula, *Theraphosa leblondi* (Theraphosidae) (Fig. 1). The tarantula had produced a silk cocoon around the head of the dead caecilian; the head was already partly digested. When disturbed, the tarantula raised its forelegs and threw urticating setae. This specimen of *O. zweifeli* is the second one known from French Guiana, the species having been recorded in that country only from a single specimen from Cayenne (Lescure and Marty, *op. cit.*).

We thank J.-C. Baloup F. Catzeflis, P Charles-Dominique, M. Dewynter, P. Gaucher, G. Lenglet, and S Lochon for working facilities.

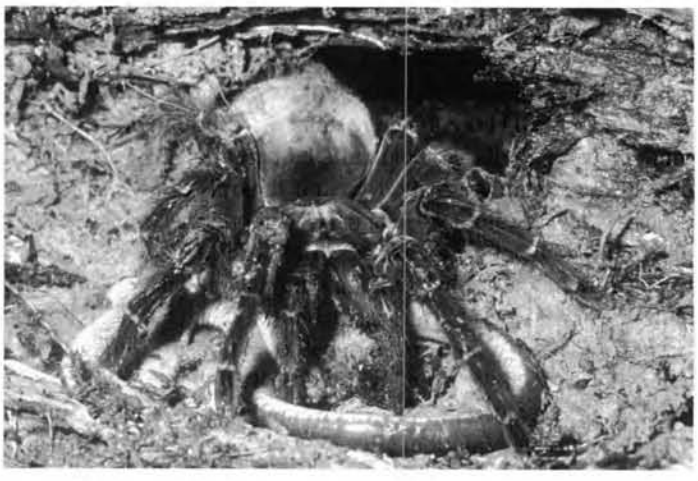

Fig. 1. Giant tarantula, *Therophosa leblondi* (Theraphosidae) preying on a Zweifel's caecilian, *Oscaecilia zweifeli*, at Nouragues Field Station, French Guiana, May 1999.

CAUDATA

AMBYSTOMA LATERALE (Blue-Spotted Salamander). **HABITAT.** On 6 April 2001, a gravid female *Ambystoma laterale* was collected at George Wyth Memorial State Park, Cedar Falls, Black Hawk County, Iowa, USA. On 7 April 2001, a male (evidenced by a swollen cloaca) was collected at the same locality. *Ambystoma laterale* are listed State Endangered by the Iowa Department of Natural Resources and are only found at two sites within the State, Behrens Ponds, Linn County, and George Wyth Memorial State Park, Black Hawk County.

Before this study, only one individual of *A. laterale* had been reported (by a park visitor) at the George Wyth Memorial State Park site (1996) since the completion of the Hwy 218 expansion project in 1989, which runs adjacent to the park. It was feared *Ambystoma laterale* had been extirpated from the George Wyth site because of the altered hydrology caused by the highway expansion. Both specimens were returned to the exact locations where they were found. Future research will concentrate on gaining an accurate estimate of the size and genetic diversity of this geographically disjunct population.

We thank Gary Dusenberry (Director of George Wyth Memorial State Park) and the students of Field Zoology at UNI for their assistance. We also thank James W. Demastes for confirming the species identification and the opportunity to search for the salamanders under Iowa DNR permit number SC-5530101.

Submitted by **DAVID WOJNOWSKI**, NCDENR/Division of Water Resources, 1611 Mail Service Center, Raleigh, North Carolina, 27699-1611, USA; **CRAIG A. MALLICOAT** and **RYAN L. WELCH**, Department of Biology, 2438 McCollum Science Hall, University of Northern Iowa, Cedar Falls, Iowa, 50614, USA.

AMBYSTOMA MACRODACTYLUM KRAUSEI (Northern Long-toed Salamander). **VOCALIZATION**. Vocalization has been documented in many terrestrial salamanders, often in association with defensive or aggressive behavior (Licth 1973. Can. J. Zool. 51:1055–1056; Brodie 1978. Copeia 1978:127–129). On 24 April 2001 at a wetland near Lost Horse Creek in the Bitterroot Mountains, Montana, USA (46°05'91"N, 114°15'82"W), a male *Ambystoma macrodactylum krausei* in breeding condition twice made a squeaking noise and three times produced a series of rapid clicks while being manipulated for photographs. The squeaks were produced with the mouth closed and might have been caused by expelling air through the nostrils. The clicks were produced by the salamander inflating its body and rapidly snapping its jaws 2–3 times. Both types of sound were audible from 0.5 m. Biological significance of the noises is uncertain because no defensive postures or aggressive movements were observed.

Submitted by **BLAKE R. HOSSACK**, Division of Biological Sciences, University of Montana, Missoula, Montana 59812, USA and Aldo Leopold Wilderness Research Institute, 790 East Beckwith Avenue, Missoula, Montana 59807, USA; e-mail: blake_hossack@usgs.gov.

DESMOGNATHUS CAROLINENSIS (Carolina Mountain Dusky Salamander) and ***PLETHODON WELLERI*** (Weller's Salamander); ***DESMOGNATHUS MONTICOLA*** (Seal Salamander) and ***DESMOGNATHUS WRIGHTI*** (Pygmy Salamander). ***GYRINOPHILUS PORPHYRITICUS*** (Spring Salamander) and ***DESMOGNATHUS OCOEE*** (Ocoee Salamander). **INTRAGUILD PREDATION**. Plethodontid salamanders are generalist predators as well as competitors, and thus fit the definition of intraguild predators (Polis et al. 1989. Annu. Rev. Ecol. Syst. 20:97–330). Hairston (1986. Amer. Nat. 127:266–291) experimentally demonstrated that both predation and competition structure salamander ensembles of *Desmognathus*. However, there is a paucity of records of interspecific predation by salamanders (perhaps because habitat partitioning effectively reduces opportunities for size-mediated predation) and the idea that predation is a significant ecological factor in structuring salamander ensembles has been questioned (Camp 1997. J. Herpetol. 31:613–616). Here I document three different predator-prey interactions based on disgorged stomach contents of wild caught salamanders. On 9 September 1995, a large (SVL 58.6 mm) gravid *Desmognathus carolinensis* was collected along Grandfather Trail on Grandfather Mt., Avery Co, North Carolina (USA) that disgorged a partially digested *Plethodon welleri* (TL 58 mm). On 20 June 1995, an adult *Desmognathus monticola* collected at Glade Gap, Nantahala Mountains, Macon Co., North Carolina disgorged a partially digested *Desmognathus wrighti*, not previously reported from this area. In September 1987 I flushed the stomach of an adult *Gyrinophilus porphyriticus* captured at Whiteside Mountain, Jackson Co., North Carolina; it disgorged a large male *Desmognathus ocoee* (SVL >50 mm).

These observations document three different predator-prey interactions involving six different species. In each case, not surprisingly, the larger individual ate the smaller individual, suggesting that body size evolution in plethodontids that coexist with other species of salamanders can drastically alter a species' role as predator or prey. For example, the large body size attained by *Desmognathus carolinensis* at high elevations throughout its range may be an example of ecological release. At these high elevation sites, it occupies a territory largely devoid of the large aquatic species (e.g., *D. monticola*, *D. quadramaculatus*, and *Gyrinophilus porphyriticus*) that normally prey upon the smaller species. Such ecological release may drive evolution of body size in high elevation populations of *D. ocoee* and *D. carolinensis* allowing these species to take on the role of dominant predator to prey upon smaller species.

Submitted by **JOSEPH BERNARDO**, Department of Biology, Frostburg State University, 101 Braddock Road, Frostburg, Maryland 21532, USA; e-mail: jbernardo@frostburg.edu.

GYRINOPHILUS PORPHYRITICUS (Spring Salamander). **MALE COMBAT**. Behavioral interactions among plethodontid

salamanders in the field are scarce, particularly in less common species, and sexual behavior of many species has never been observed in the field (Arnold 1977. *In* Taylor and Guttman [eds.], Reproductive Biology of Amphibians, pp. 141–183, Plenum Press, New York). There is little published information about sexual behavior in spring salamanders. Bishop (1941. Salamanders of New York. Bull. New York State Mus. No. 324, Albany, New York) provided a detailed description (pp. 243–244) of an interaction between two specimens in the field, that he presumed to be a courting pair. This observation was also reported by Petranka (1998. Salamanders of the United States and Canada. Smithsonian. Inst. Press, Washington, D.C.). Bishop's description of *Gyrinophilus* courtship differs significantly from the elaborate courtship including tail-straddle walk that typifies courtship in the Plethodontidae (Arnold 1977, *op. cit.*) and that reported for closely related *Pseudotriton* (Organ and Organ 1968. Copeia 1968:217–223). It also differs from the description provided by Beachy (1997. Herpetologica 53:289–296) based on extensive observations from staged laboratory encounters.

On 21 September 1995 at Whiteside Mountain, Jackson County, North Carolina (USA), we encountered two large (SVL 86.7 mm and 90.6 mm) *G. porphyriticus* engaged in behavior remarkably similar to that described by Bishop. The two salamanders were in a shallow pool (~10 cm) in a small stream at the base of a rock face. The animals wrestled and writhed while biting each other aggressively. The behavior we observed resembled the aggressive interactions reported for many species of plethodontids (reviewed by Arnold 1977, *op. cit.*). After watching the salamanders engage in this behavior for about 10 minutes, they were collected and sacrificed the next day. Dissection revealed that both individuals were males, meaning that these behavioral interactions and probably those reported by Bishop (1941, *op. cit.*) are male-male agonistic behavior (sexual interference: Arnold 1976. Z. Tierpsychol. 42:247–300) rather than courtship behavior. The two specimens have been deposited in the North Carolina State Museum of Natural Sciences (NCSM 62159–62160).

NECTURUS MACULOSUS (Mudpuppy). **PREDATION**. Predation on mudpuppies is not well documented. Herein I report predation on mudpuppies by mink (*Mustela vison*). During July 2001, Steven and Maureen Maslak of Rome, Maine, observed an adult mink carrying a mudpuppy in its mouth on the shore of Long Pond. The Maslaks often observe mink at this site, and often capture mudpuppies in their minnow traps. To my knowledge this is the first report of such predation.

Submitted by **MICHAEL J. LITTLE**, 82A Summer Street, Waterville, Maine 04901, USA; e-mail: brca@gwi.net.

NOTOPHTHALMUS VIRIDESCENS (Eastern Red-Spotted Newt). **PREDATION**. No significant predation on adult eastern red-spotted newts, *Notophthalmus viridescens*, has been documented in the wild. Natural predation on the toxic adult newts might help explain their cryptic dorsal coloration.

During late September 1998, two female newts were placed in a minnow trap overnight in Binghamton University's Nature Preserve pond (Broome County, New York, USA), and one experienced limb and tail predation that provided the impetus for further investigation of newt predation. At 1700 h on 25 September and 2 and 9 October 2000 at the same site, three newts were placed in each of nine minnow traps set ca. 7 m apart, 45 cm deep, and 1.0 m from shore. Trap checks at 1000 h the following mornings revealed no newt captures. On 26 September, two of the 27 newts had disappeared and 11 had serious or fatal injuries: all lost limbs (Fig. 1), four had partial or total tail loss, and one had only the spine, head, and dorsal skin remaining (Fig. 2). On 3 October, one of the 27 newts was missing and one had lost a limb. No newts were injured or missing on 10 October. The first frost of the year occurred between the first and second trapping sessions, and two frosts occurred between the second and third. Injuries seemed to have been inflicted from outside the traps because many newts were found with their bodies partially pulled through the trap mesh. The predation seems to be crepuscular or nocturnal, as we have over 1500 newt captures in 3000 h of diurnal trapping (1000–1700 h) at the same population from March until June of 1999 and 2000 without an incident of predation (unpublished).

FIG. 1. Examples of limb predation on adult *Notophthalmus viridescens*.

These are the first observations of natural and significant preda-

FIG. 2. Example of tail and ventral surface predation on adult *Notophthalmus viridescens*.

tion on adult eastern red-spotted newts. Many predator species can be ruled out either because they are not found at our site (crayfish), were concurrently captured in traps with newts during the day without predation (fish, dragonfly larvae), repeatedly reject newts as food (fish, water snakes, garter snakes: Hurlbert 1970. J. Herpetol. 4:47–55), are diurnal foragers (painted turtles: Johnson 1997. The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, Missouri. 163 pp.), or are incapable of removing newt limbs (water beetles and bugs have piercing mouthparts: Peckarsky et al. 1990. Freshwater Macroinvertebrates of Northeastern North America. Cornell University Press, Ithaca, New York. 138 pp.). However, snapping turtles (*Chelydra serpentina*) have consumed adult newts and newt limbs in the laboratory (Hurlbert, *op. cit.*), and use a combination of sucking and rapid head movements to bite off sections of prey (Lagler 1943. Am. Midl. Nat. 29:257–312), which would be necessary to draw newt limbs through the trap mesh for seizing. Additionally, at a similar latitude (ca. 45°N, Ontario, Canada), snapping turtles are crepuscular and entered winter dormancy as temperatures dropped during October, matching the timing of our predation declines (Obbard and Brooks 1981. Copeia 1981:630–637). Future studies will confirm whether snapping turtles consume newts in the wild.

SPELEOMANTES AMBROSII (Ambrosi's Cave Salamander). **ALBINISM**. The European plethodontid salamander *Speleomantes ambrosii* is endemic to a small area between Tuscany and Liguria in NW Italy (Lanza et al. 1995. Mus. Reg. Sci. Nat., Monografie, Torion, 16:368 pp.). While conducting research in a karstic area near the town of La Spezis (Liguria), an albino adult female *S. ambrosii* (SVL 65 mm; mass 3.8 g) was observed on 5 and 12 August 2001 in an artificial tunnel with several other normally-pigmented individuals. The specimen had reddish eyes with blood vessels visible through the skin (Fig 1.). Only light yellow pigmentation was visible on the back, and thus this salamander can be considered a partial albino with xanthophores (Drykacz 1981. SSAR Herpetol. Circ. 11:131 pp.). This is the first report of albinism in the European plethodontid salamander genus *Speleomantes*.

FIG. 1. The albino female *Speleomantes ambrosii* from La Spezia, Liguria NW.

Herpetological research on cave salamanders was authorized by Italian Ministry of Environment (research permit 98-028-CC-98-13).

ANURA

ASCAPHUS TRUEI (Tailed Frog). **ALBINISM**. On 8 July 1996, we captured an albino *Ascaphus truei* larva in the South Fork of Quartz Creek, Clatsop County in the northern Coast Range of Oregon, USA. The larva was of similar developmental stage (rear limb buds) and size as other non-albino larvae captured during that sample (mean ± SD: SVL 13.1 ± 2.0 mm, TL 40.3 ± 2.7 mm; N = 73). The larva was almost completely lacking pigmentation on dorsal and ventral surfaces, but possessed a slight pink/orange hue, which was more concentrated in the eyes. Its coloration contrasted markedly with other larvae from the site, which were predominately the more typical dark brown or black. The animal thus fits the description of an albino (Dyrkacz 1981. SSAR Circular No. 11. 31 pp.). To our knowledge, there are no instances of albinism or leucisticism reported for *Ascaphus truei*, a primitive anuran endemic to the Pacific Northwestern U.S. and southwestern Canada. The frequency of albinism in *Ascaphus truei* remains unknown, but our surveys over the last 4+ years have revealed no other examples in Oregon.

BUFO CALIFORNICUS (California Arroyo Toad). **HABITAT and POPULATION STATUS.** In the coastal and foothill drainages of southern California and northwestern Baja California, Mexico, populations of the endangered *Bufo californicus* are often associated with open to partially open stream terraces, shallow permanent or intermittent streams and pools, and sand and gravel stream bottoms free of vegetation from periodic flooding (McLaughlin and Stephenson 2001. Fed. Register 66[26]:9414–9474). Although several authors have studied the species' ecology in coastal drainages and, to a lesser extent, in upland habitats of southern California, reports on the natural history, distribution, and status of *B. californicus* in Baja California are lacking (U.S.

Fish and Wildlife Service 1999. Arroyo southwestern toad (*Bufo microscaphus californicus*) Recovery Plan. USFWS, Portland, Oregon. 119 pp.). Currently, *B. californicus* is distributed disjunctly in northwestern Baja California from the coastal plains (e.g., Río San Vicente, Río San Telmo, Río Santo Domingo), inland foothills (e.g., Cañon Agua Caliente, Ojos Negros, Río Valladores, Rancho San Antonio, Arroyo San Rafael), peninsular range of the Sierra San Pedro Mártir (e.g., Misión San Pedro Mártir, La Grulla at 2157 m, Santo Tomás), and south to Arroyo Simón, ca. 16 km southeast of San Quintín (Gergus et al. 1997. Herpetol. Rev. 28:47).

We report on the habitat, recruitment, and present status of a new population of *Bufo californicus* in the coastal drainage of the Río Guadalupe, La Misión (La Misión de San Miguel), Baja California, México. The Río Guadalupe and its tributaries, herein recognizied as a third order stream (see Sweet 1992. Initial Report on the Ecology and Status of the Arroyo Toad [*Bufo microscaphus californicus*] on the Los Padres National Forest of southern California, with management recommendations. Report USDA Forest Service, Los Padres National Forest, Goleta, California), meanders nearly 90 km west of its headwaters in the western foothills of the Sierra Juarez (elev. 1700 m) and drains ca. 1960 km^2 of watershed before reaching the Pacific Ocean.

We conducted surveys at three sites, Puente La Misión (32°5.838'N, 116° 51.344'W, elev. 9 m), Cañada Los Alisos (32°6.103'N, 116°48.495'W, elev. 19 m), and Rancho Viejo (32° 5.913'N, 116° 47.425'W, elev. 23 m) during April–July 2001. These sites are within the coastal Río Guadalupe drainage (stream length 7 km, stream gradient 2 m/km) in close proximity to where *B. californicus* were previously observed (C. Mahrdt, 1995 unpubl. field notes). The westernmost Puente La Misión site is located 2.4 km east of the Pacific Ocean and 0.8 km east of any tidal influence. Since 1973, the habitat of the lower drainage has been severely altered by grazing, agriculture, dredging, and sand mining activities and within the last four years these activities have extended nearly 3 km upstream (Mahrdt, pers. obs.). Numerous man-made cattail (*Typha* sp.) ponds and channels < 2.5m in depth in association with stockpiles of alluvial sand and rock currently are scattered throughout much of the drainage. The extensive streambed alteration has resulted in a series of barren to sparsely vegetated stream terraces dominated by non-native vegetation (e.g, *Tamarisk* sp., *Bromus* sp.) along with relictual and recruiting native vegetation (e.g., *Baccharis* sp., *Iva* sp.). Further upstream, several ponds < 0.5 m in depth fed by subsurface aquifers have been created because of the heavy mining and export of alluvial soils. These ponds were largely unvegetated, although some of the presumably older basins supported large, floating mats of *Ceratophyllum* sp. and isolated patches of cattail. In addition, these ponds occurred on and were surrounded by barren unconsolidated alluvium with a sparse scatter of herbs (*Sonchus* sp.) and seedling shrubs (*Nicotiana* sp., *Salix* sp.).

On 14 April, two of us (CRM and SJZ) conducted a nocturnal survey along a 200 m portion of stream at the Puente La Misión site. At 2205 h, 12 males were calling and a pair was observed in amplexus in a shallow (< 10 cm), slow moving stream covered with a dense layer of algae and watercress (*Rorippa* sp.). Larvae were observed in large numbers (ca. 200) in small pools made by the hoof prints of horse and cattle. The air temperature was 10.8°C and the relative humidity 81% at 2200 h. The streambed lacked a gravel or pebble substrate and was composed of fine sandy-clay soil covered by a dense and heavily grazed mat of non-native grasses, (e.g., *Paspalum* sp.) intermixed to a lesser extent with a variety of herbaceous annuals, (e.g., *Ranunculus* sp., *Cotula* sp., *Anemopsis californica*, *Anagallis* sp., *Plantago major*), seedling shrubs (e.g., *N. glauca*, *Salix* sp.), and halophytes (e.g. *Heliotropium* sp., *Distichlis* sp.).

During the evening (ca. 2100–2330 h) of 8 June and morning (ca. 0630–0830 h) of 9 June, two of us (CRM and REL) conducted surveys at all three sites. At Puente La Misión, only one subadult *B. californicus* (SVL 52 mm; mass 16 g) was seen active on the stream terrace at 2150 h. Adult toads, metamorphs, and tadpoles were not observed although predators such as crayfish (*Procambarus* sp.) and bullfrog (*Rana catesbeiana*) were present in the stream. Further upstream at the Cañada Los Alisos site, six adult male toads (SVL 68–72 mm; mass 32–41 g) were seen at night (2230–2330 h) in shallow water at the edge of a recently constructed 0.5 ha pond. Approximately 100 metamorphs (SVL < 2 cm) were found on the steep banks of the pond and associated artificial terraces. During the cool overcast conditions that morning, metamophs (ca. 300) were present on quarry roads and terraces within 100 m of six artificial ponds (0.25–0.75 ha) along 2 km of riverbottom at the Rancho Viejo site. Metamorphs occurred along with low numbers of juvenile *Hyla regilla* and *Bufo boreas* and were highly conspicuous against the sparse vegetation and open sand terraces at recently quarried sites. Several juvenile *B. californicus* were found crushed presumably by sand and gravel truck traffic in this area.

A daytime inspection (0945–1245 h) of the sites by CRM and SJZ on 22 July failed to locate *B. californicus* of any life stage. The stream at the Puente La Misión site and smaller ponds at the Rancho Viejo site had dried up since our 8 June visit.

Our observations suggest that artifical ponds and man-made stream terraces may play a role in the breeding biology of *B. californicus*. Price and Sullivan (1988. Cat. Amer. Amphib. Rept. 415.1–415.3) commented on the increased utilization of artificial habitat sites of *B. californicus*. Although anthropogenic habitat modification (e.g., grading, off-road vehicle use, overgrazing, mining, and dredging) has clearly contributed to the decline of *B. californicus* populations (Sweet, *op. cit.*), some aspects of these disturbances might contribute to an increase in potential breeding sites and recuritment, at least in the short term. Sand mining of the Río Guadalupe has eliminated most of the vegetative cover and has created large areas of exposed, friable alluvium proximal to shallow pools. In this case, such a disturbance might be beneficial in that it mimics the effects of natural disruptive forces (e.g., seasonal floods) which ordinarily create open terraces and shallow oxbow pools in high-energy, dynamic river systems such as the Río Guadalupe. Stream alteration and the construction of wells and pumping stations are used to supply water to the nearby agricultural areas. It is not clear what effect the region's hydrology might have on the long-term viability of *B. californicus*; however, any substantial drop in water table depth would be expected to attenuate the river's capacity to flood and subsequently scour adjacent creek terraces. Future surveys in the Río Guadalupe drainage as well as other major drainages and their tributaries in northwest Baja California will help provide a more thorough understanding of the distribution, habitat characteristics, and popula-

tion trends of *B. californicus* in this region.

We thank B. D. Hollingsworth and K. R. Beaman for comments and criticisms on the manuscript and providing museum locality records. We extend our gratitude to C. Brown for his efforts in photographing various aspects of the coastal Río Guadalupe drainage. Voucher slides were deposited at the Los Angeles County Museum of Natural History (LACM-PC 1365a–e).

BUFO FOWLERI (Fowler's Toad). **PREDATION.** *Bufo fowleri* reaches its northern limit in Ontario, Canada on the Lake Erie shoreline (Green 1989. Can. Field Nat. 103:486–496). In Canada it is listed as a threatened species (Committee on the Status of Endangered Wildlife in Canada) largely because of disjunct populations and fluctuating abundance (Green 1997. Herpetol. Conserv. 1:45–56). Although threatened, there is little information regarding *B. fowleri* predators in Canada. Herein we report observations made of predation on a male *B. fowleri* by a male bullfrog (*Rana catesbeiana*).

On 11 May 2001, a male *R. catesbeiana* was spotted at a known *Bufo fowleri* breeding pond. Upon hand capture, the bullfrog 'screamed' and it was possible to see *B. fowleri* hind limbs inside the bullfrog's throat. The toad was immobile and covered in mucus after removal from the bullfrog (Fig. 1). The toad was kept in a plastic bag, until movement returned (two hours), and then released at the same location the next day. These observations were made in a dune pond near Long Point Ontario, Canada (N42.575686, W080.472468). The area is locally dominated by *Typha* sp., *Populus* sp., and in the spring of 2001 was ca. 60 m from the Lake Erie shoreline.

ELEUTHERODACTYLUS FITZINGERI (Common Rain Frog). **CLUTCH SIZE and PARENTAL CARE.** On 29 March 2001 we found a brooding adult female (SVL 51 mm) *Eleutherodactylus fitzingeri*. The specimen was under a pile of sticks and coffee leaf litter, 4.38 km SE San Vito, Los Angeles (08°47'22.4"N, 82°56'40.1"W, 1006 m elev.), Coto Brus District, Puntarenas Province, Costa Rica. The original vegetation (pre-montane rain forest; Holdridge et al. 1971. Forest Environments in Tropical Life Zones: A Pilot Study. Pergamon Press) had been transformed into coffee plantations and pasture lands. The nest was in a small cavity on the ground and contained a clutch of 85 eggs (each ca. 2 mm diameter) The clutch of round and yellowish eggs was bunch-shaped and without jelly or foam to join or to protect the eggs. When we removed the sticks and leaves the female remained over the nest in a protective attitude. However, when the female was picked up she voided urine, perhaps as a defensive behavior. When the female was returned to the nest site, she again covered the nest with her body. Color slides of the specimen were taken and deposited at the Museo de Zoología, Facultad de Ciencias, UNAM slide collection.

EPIPEDOBATES FEMORALIS (NCN). **DIET.** The dendrobatid frog *Epipedobates femoralis* occurs in the lowland forests of Guyana, Surinam, and French Guiana, and in the Amazon drainage of Colombia, Ecuador, Peru, and Brazil (Frost 2000. Amphibian Species of the World: An Online Reference V2.20 [September 2000]). On 18 February 2001 we captured a female *E. femoralis* (33 mm TL) at Reserva Florestal Adolfo Ducke, Amazonas, Brazil (03°08'S, 60°04'W). Upon capture the frog immediately regurgitated a live juvenile *Anolis fuscoauratus* (40 mm SVL). The lizard remained immobile for 20 minutes, and then walked off. Due to the lack of collecting permits, the lizard and frog were released.

Ants and termites are the main diet of *E. femoralis* (Toft 1980. Oecologia [Berlin] 45:131–141; Caldwell 1996. J. Zool. London 240:75–101). To our knowledge, this is the first report of predation on lizards by frogs in the family Dendrobatidae.

Financial support was provided to A.P. Lima by CNPq (Auxílio a Pesquisa Nº 460233/00-9).

Submitted by **GRAZIELA M. BIAVATI**, **ALBERTINA P. LIMA**, and **CAROLINA TOSI**, Coordenação de Pesquisas em Ecologia, Instituto Nacional Pesquisas da Amazônia, CP 478, 69011-970, Manaus, Amazonas, Brazil.

HYLA PUNCTATA (NCN). **DIET.** *Hyla punctata* is widely distributed in the Neotropical region, from Colombia to French Guiana and south through Brazil, Bolivia, and Paraguay. Within Argentina, it occurs in the provinces of Formosa and Chaco (Cei 1980. Amphibians of Argentina. Monit. Zool. Ital. [NS] Monog. 2:609).

TABLE 1. Prey consumed by *Hyla punctata* (N = 19) from Santa Fe Province, Argentina. No. = number of prey items; % Total = percentage taxa in the total number of prey; % Vol = percentage of each prey volume (mm^3); Freq. = number specimens containing prey; % Occ. = percentage occurrence.

TOTAL	79	100%	100%	—	—

Although many aspects of ecology of *Hyla punctata* were discussed by Gallardo (1987. Anfibios Argentinos. Guía para su Identificación. Biblioteca Mosaico, 98 pp.) the diet of this hylid frog has not been described.

Between 15 December 1999 and 2 February 2001 we collected 19 specimens (8 males, mean SVL = 20.23 mm ± 8.81 mm and 11 females, mean SVL = 19.35 mm ± 3.06 mm). The samples were taken in two semi-permanent ponds of Santa Fe Province, Argentina (31°35'S, 60°41'W). Frogs were captured by hand between 2000 and 2300 h and preserved in 10% formalin. Analysis of the stomach contents suggests that *H. punctata* has a carnivorous diet, composed mainly of arthropods. The most frequently taken prey items were dipterans (N = 45; 57%) and hymenopterans (N = 16; 20%). These results suggest that *H. punctata* has a sit and wait foraging behavior for capturing prey. Table 1 summarizes these results.

LIMNONECTES LIMNOCHARIS (Paddy Frog): **PREDATION.** Herein we report predation of *Limnonectes limnocharis* by four species of colubrid snakes collected during July 1989 at a single locality in west-central Thailand, precisely 25 km NW of Lan-Sak, 65 km NW of Uthai-Thani, ca. 220 km NW Bangkok, 110 m elevation, in Uthai Thani Province. Juvenile *L. limnocharis* were found in the stomachs of the following snakes: one in a *Dendrelaphis pictus* (Institut Royal des Sciences naturelles de Belgique IRSNB 15587; SVL 497 mm), two in a *Enhydris plumbea* (IRSNB 15589; SVL 215 mm), one in a *Ptyas korros* (IRSNB 15590; SVL 826 mm), three in a *Xenochrophis flavipunctatus* (IRSNB 155927; SVL 340 mm), and one in another *X. flavipunctatus* (IRSNB 15593; SVL 297 mm). No other prey items were detected in the stomach of these snakes. Although the list of ophidian predators on *L. limnocharis* at Lan-Sak is undoubtedly longer, this report is indicative of the high predation pressure on *L. limnocharis* at some localities and hence its importance in the local trophic chain.

We thank G. Lenglet, G. Coulon (IRSNB) and R. Peuchot (Universite Libre de Bruxelles, Brussels).

PHYLLOMEDUSA HYPOCHONDRIALIS AZUREA (Orange-legged Leaf Frog). **METAMORPH BEHAVIOR.** Wiping of skin secretions in metamorphic *Phyllomedusa hypochondrialis azurea* is reported. The specimen (SVL 2.08 cm) was collected on 8 Dec 2000, near the town of Tavaí, Reserva San Rafael (26°18'27"S; 55°40'29"W), Department of Cazaapá, Paraguay during a survey conducted by the Natural History Museum and Biodiversity Research Center (KUNHM BRC) of the University of Kansas and the Museo Nacional de Historia Natural del Paraguay (MNHNP). The specimen was collected at night in 0.5 m high grass, at the edge of a cattle pond utilized by several species of anurans; humidity was high and the temperature was ca. 26°C. On the following day, we observed the wiping behavior at mid-day (1100 h) while the metamorph was perched on a branch. Mid-day temperatures during this behavior were ca. 37.7°C. The specimen is deposited at KUNHM BRC (KU 290892).

The behavior was consistent with the description by Blayloch (1976. Copeia 1976:283–295) and began with the frog rubbing its dorsum and pelvic region with the hind limbs. Secretions appeared to be concentrated on the dorsum of the pelvic region, where lipid glands presumably are present in metamorphs as well as adults (Fig. 1). The right foot was raised and pronated to grasp and wipe the right flank and left leg; subsequently the dorsum was wiped posteriorly-anteriorly. Once the parotoid gland was reached, the metamorph proceeded to wipe its shoulder, elbow, and forearm. While the forearm was being wiped, the dorsal surface of the femur was also reached and covered with secretions. This motion was repeated on the left side with the left foot. A more intricate, scissors-like pattern of wiping the femurs was employed, with both feet wiping simultaneously, the right foot wiping the left and visa versa. After wiping the back, the juvenile used its hands to smear the head and chest with secretions (Fig. 2). Wiping the head began by pronating the hand and grasping the parotoid region, with Digit I (i.e., thumb) directed ventrally and Digits II-IV directed dorsomedially over the parotoid gland. Wiping of the body with

FIG. 1. Regularly arranged dorsal glands of *Phyllomedusa hypochondrialis azurea*.

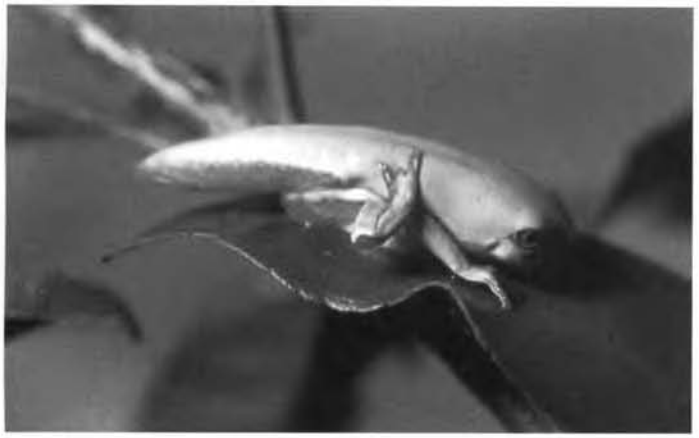

FIG. 2. *Phyllomedusa hypochondrialis azurea* metamorph wiping secretions on its body with pronating hind limb.

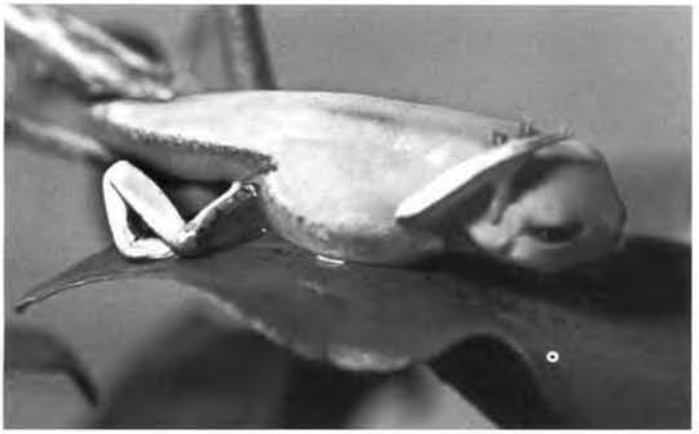

FIG. 3. Metamorph wiping secretions on its head with pronating forelimb.

the forelimb began at the parotoid, then progressed towards the face and snout, and postventrally over the belly. Once a wiping motion was initiated, the individual would continue it to a certain point and would restart from the original point of initiation; rubbing was not observed. When the entire body had been wiped, the juvenile entered a torpid state. To our knowledge, this is the first report of wiping behavior in a phyllomedusine metamorph, and may be the first for any anuran metamorph.

We thank J. Simmons and Nancy Lopez de Kolchalka for directing the KUNHM BRC and the MNHNP participation in a herpetofaunal survey of the Reserva de San Rafael. We also thank C. A. Sheil, O. Torres, and L. Trueb for suggesting revisions to improve this manuscript.

PLETHODONTOHYLA TUBERATA (NCN). **DEFENSIVE BEHAVIOR**. During a herpetological survey in January 1993 at Forestry Station of Manjakatompo (Ankaratra Massif, Antananarivo Province, Madagascar; 19°21'S, 47°18'E; ca. 1700 m), we observed a peculiar defensive behavior of the cophyline microhylid *Plethodontohyla tuberata*. The individual (a male) was captured and handled to be photographed. Disturbed, it lowered the head, closed the eyes, and inflated the body. More or less simultaneously the frog extended the hindlimbs and, hanging on the inner side of the feet, he elevated the posterior part of the body, showing light spots, which are usually hidden in the inner surface of the thighs. The dorsal dermal glands exuded copious quantities of a thick, whitish, and sticky secretion. This secretion was visible on the back for several minutes, later losing its density and color. Such a defensive behavior is not associated with an overall aposematic coloration, although the inguinal spots in this and in related species (e.g., *P. laevipes*) have an evident aposematic significance. Such a defensive behavior has not been documented previously in the genus *Plethodontohyla*. However, a comparable behavior was reported for *Balebreviceps hillmani* from Ethiopia, (Largen and Drewes 1989. Trop. Zool. 2:13–30). Among the Malagasy microhylids, a similar antipredator strategy is known in the tomato frog, *Dyscophus antongili* (Pintak 1987. Salamandra 23[2/3]:106–121). However, in *D. antongili* inflation of the body and the production of a toxic secretion is accompanied by a clear aposematic (orange-red) coloration.

PSEUDACRIS TRISERIATA TRISERIATA (Western Chorus Frog). **REPRODUCTION.** Western chorus frogs (*Pseudacris triseriata triseriata*) are small, spring-breeding amphibians common to south-central Ontario (Weller and Oldham 1988. The Ontario Herpetofaunal Summary. Ontario Field Herpetologists, Cambridge, Ontario). There has been little information reported regarding their reproduction (Hecnar and Hecnar 1999. Herpetol. Rev. 30:38) despite their common occurrence. Herein I report observations of apparently communal chorus frog egg deposition.

In late April and early May 1997, 1998, and 1999, I observed chorus frog males calling from the periphery of what I propose was a site of communal egg deposition. The site was ca. 80 cm in diameter and contained 70 egg masses with eggs ranging from Gosner Stage 11–22 (Gosner 1960. Herpetologica 16:183–190). Egg masses were ca. 4–5 cm long and contained 20–50 eggs. These observations were made on the campus of Trent University (44°21'N, 78°17'W) in the Kawartha Region of south-central Ontario. The area is locally dominated by willow (*Salix* sp.) and contained numerous temporary vernal pools. No other calling congregations were observed at nearby pools and no egg masses were discovered in adjacent pools. This is the first report of potentially communal egg deposition for this species.

I thank the Natural Sciences and Engineering Research Council (NSERD, Canada) for supporting my field research during this observation.

PSEUDOPALUDICOLA FALCIPES (NCN). **DIET.** *Pseudopaludicola falcipes* is a very small (to 1.4 cm SUL), common leptodactylid frog. It is found in Argentina, southern Brazil, Paraguay, and Uruguay. The diet of 20 *P. falcipes* (8 males; 12 females) captured 15 km NE Corrientes City (27°28'S, 58°50'W), Corrientes Province, Argentina during March–May 1997 consisted of ten prey categories, dominated numerically by acari (N = 137; 52.3%) and volumetrically by coleopterans (6.10 cm^3 x 10^3; 30.9%). Collembolans were encountered most frequently (15). The values of prey diversity calculated by Shannon's index (H') and niche amplitude by Levins's index, were 1.24 and 2.56, respectively. *Pseudopaludicola falcipes* is a widely foraging predator with a generalized arthropod diet. Table 1 summarizes data collected during this study.

I thank Arturo I. Kehr for suggestions regarding this manuscript.

RANA AURORA AURORA (Northern Red-legged Frog). **DIET.** Diet data for northern red-legged frogs (*Rana aurora aurora*) indicate that they consume mostly insects and slugs (Fitch 1936. Amer. Midl. Nat. 17:634–652; Licht 1986. Can. Field Nat. 100:22–31). No vertebrate prey has been reported for this species. The closely related, larger California red-legged frog (*Rana aurora draytonii*) is known to take vertebrate prey with some frequency (Hayes and Tennant 1986. Southwest. Nat. 30:601–605), but with a reported maximum size of ca. 100 mm SVL (Storm 1960. Herpetologica 16:251–259; Hayes and Miyamoto 1984. Copeia 1984:1018–1022), the ability of *R. a. aurora* to take vertebrate prey is likely restricted to smaller taxa. Herein, we provide the first report of a *R. a. aurora* predation attempt on a vertebrate.

On 26 September 2000 between 1015 and 1115 h, we surveyed a small (ca. 6 m^2), isolated seepage in the Stillman Basin, Lewis County, southwestern Washington, USA. This seep, located in a 55-year-old, managed Douglas-fir stand, had a mud substrate, little (< 1 m^2) standing water, two large (≥ 50 cm diam) decayed logs, a few skunk cabbage (*Lysichiton americanum*), and one large black cottonwood (*Populus balsamifera*). Searching beneath woody debris next to the logs revealed an adult (45 mm SVL, 2.2 g) male Columbia torrent salamander (*Rhyacotriton kezeri*). Less than one minute following its release, we detected an adult (80 mm SVL, 70.5 g) female *R. a. aurora* nearby. When we examined the frog a few minutes later, it opened its mouth slowly, and a living male *R. kezeri* emerged headfirst. The salamander seemed unharmed, and based on its size and mass, was believed to be the same animal previously captured.

We do not know if the *R. aurora* would have eaten the *R. kezeri* had the frog not been disturbed. We also do not know if the frog released the salamander because of handling or because the salamander was unpalatable. Shrews reject *Rhyacotriton* (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest), and their reduced palatability has been demonstrated for Pacific giant salamanders (*Dicamptodon tenebrosus*: Rundio and Olson. 2001. J. Herpetol. 35:133–136).

These observations were made as part of a headwater stream study funded by Washington State Department of Natural Resources and conducted by the Washington Department of Fish and Wildlife through the Landscape and Wildlife Advisory Group and the Amphibian Research Consortium.

RANA CAPITO CAPITO (Carolina Gopher Frog). **REFUGIA.** Except during its breeding season when it visits temporary ponds, the gopher frog (*Rana capito* ssp.) is terrestrial and inhabits animal burrows, stump holes, and other ground cavities. In this note we report the unique appearance of burrows used by *Rana capito capito* in the Atlantic Coastal Plain of southeastern Georgia, USA.

On 7 October 1999 at 1430 h, we observed an adult gopher frog near a small burrow in dry longleaf pine (*Pinus palustris*)–wiregrass (*Aristida beyrichiana*) flatwoods habitat on the Fort Stewart Military Installation, Long County, Georgia. The frog quickly moved into the burrow as we approached. The entrance was well-worn and smooth-sided with a "platform" of bare ground-ca. 13 x 9 cm-along one edge of the burrow (Fig. 1). When we returned to this site on 11 January 2000 the burrow appeared the same. We excavated the burrow and found an adult gopher frog (83 mm SVL) at the bottom of the burrow. The burrow measured 3.4 cm wide at the entrance, and sloped at ca. 45° angle for ca. 51 cm (to a depth of 36 cm). The burrow was clean of debris along its entire length.

A second nearby burrow, assumed to contain a gopher frog because of its similar size and appearance, was also excavated. This

FIG. 1. Burrow inhabited by adult *Rana capito capito* (Long County, Georgia).

burrow possessed a smooth-sided entrance (4.2 cm wide at entrance) and a "platform" (11.6 x 9.8 cm) from April 1999 (when first discovered) until 13 January 2000 (when excavated). For a short distance this burrow descended into the soil at a 45° angle, but it then paralleled the ground surface for ca. 135 cm before connecting (at a depth of 41 cm) to the shaft of an abandoned gopher tortoise (*Gopherus polyphemus*) burrow. Just before this burrow connected to the abandoned tortoise burrow, we found an adult gopher frog (69 mm SVL).

The gopher frog's habit of sheltering in gopher tortoise burrows and other animal burrows, including those of the oldfield mouse (*Peromyscus polionotus*), has long been recognized (Carr 1940. Univ. Florida Publ., Biol. Sci. Ser. 3:1–118). Gopher tortoise and oldfield mice are common at the site mentioned above where we excavated gopher frogs from small burrows. Based on its length and angle of descent, we believe that the first burrow described above might have been an abandoned *P. polionotus* burrow (see Lee 1968. Herpetologica 24:83–84 for a description of *P. polionotus* burrows). Gentry and Smith (1968. J. Mammal. 49:562–565) excavated "numerous" gopher frogs from *P. polionotus* burrows, but only from burrows that were no longer occupied by mice.

Although we have yet to test this prediction, an ability to identify small burrows occupied by gopher frogs based on the rather unique appearance of the burrows at their entrances (i.e., smooth-sided entrances and bare "platform") might have some merit for locating frogs or new frog populations, especially at pine flatwoods sites where herbaceous plants, debris, and litter have been removed or trimmed back by recent fire events.

Submitted by **DIRK J. STEVENSON** and **KAREN J. DYER**, Fort Stewart Fish and Wildlife Branch, Directorate of Public Works, 1113 Frank Cochran Drive, Fort Stewart, Georgia USA, 31314-4940 (e-mail:stevensond@emh5.stewart.army.mil).

RANA CATESBEIANA (American Bullfrog). **DIET**. Data were obtained opportunistically from 28 adult (14 M; 14 F) bullfrogs collected during April 2001 from Meadow Valley Wash located between the cities of Carp and Elgin, Lincoln County, Nevada, USA (37°17'N, 114°30'W). Although there are two summary reports that provide publication lists of bullfrog food/diet literature (Bury and Whelan 1984. Ecology and Management of the Bullfrog. USDI, FWS Resource Publ. 155. 23 pp.; Casper and Hendricks, *in press*. *In* M. J. Lannoo [ed.], Status and Conservation of U.S. Amphibians. Univ. California Press, Berkeley), there are, to our knowledge, no published bullfrog diets from this region.

Bullfrogs were collected by gigging. After collection, bullfrogs were weighed to the nearest gram and measured from the tip of the snout to the vent (to the nearest millimeter). After the hindlegs were removed by the sportsmen, the frogs were placed on ice in plastic bags and transported to the laboratory. Stomachs were dissected and preserved in 10% formalin.

Several weeks after collection, stomach contents were rinsed with 70% ethanol, and separated into the following categories: food items, unidentifiable boluses, plant material, and rocks. A wet mass was obtained prior to identification (Table 1). Food items were identified minimally to order, and to family and/or genus in most instances (Table 2).

Nearly all stomachs examined contained food items or digested food boluses (86% M; 100% F). No statistical differences were detectable between males and females when comparing the means from various measurements (Table 1; independent t-tests all resulted in $P > 0.05$). Further, no relationship was found between total wet mass of ingested items and frog length and mass for either sex (linear regression, $P > 0.05$ in all cases). Interestingly, there were significant inverse relationships between female length and mass and the diversity of food items in the stomach, wherein smaller females had a higher diversity of food items (linear regression: diversity vs. length, $P = 0.028$; diversity vs. mass, $P = 0.038$); this relationship was not true for males. The variety of ingested items, including the large number of stomachs containing plant material and rocks, supports the notion that bullfrogs have voracious appetites and will swallow anything taken into their mouths.

TABLE 1. Means (sample sizes; standard errors) for selected measurements from 28 adult *Rana catesbeiana* collected in Meadow Valley Wash between Carp and Elgin, Lincoln County, Nevada in April 2001. Female sample size for Simpson's Diversity Index is not 14 as one female contained an unidentifiable food bolus, and diversity could not be calculated. Frog length was measured snout-to-vent.

Gender	Frog length (mm)	Frog mass (g)	Food items (g)	Plant matter (g)	Rocks (g)	Total gut wet mass (g)	Simpson's Diversity Index
Female	127.00 (14; 5.21)	210.15 (14; 23.45)	1.60 (13; 0.36)	2.30 (11; 0.81)	3.78 (4; 2.81)	4.48 (14; 1.06)	3.04 (13; 0.36)
Male	140.21 (14; 4.43)	275.64 (14; 25.47)	2.13 (12; 0.66)	1.56 (8; 0.63)	1.7 (3; 0.95)	3.08 (14; 0.98)	2.74 (14; 0.48)

RANA CATESBEIANA (Bullfrog). **DIET.** As part of a study of *Thamnophis gigas* at Colusa National Wildlife Refuge, Colusa County, California, we investigated to what extent non-native *Rana catesbeiana* preyed on these endemic aquatic snakes, which are federally and state listed as Threatened. Predation on young water snakes is thought to be a significant source of mortality for snake populations (Mushinsky and Miller 1993. Copeia 1993:660–665) and bullfrogs have been shown (Willis et al. 1982. Copeia 1982:98–10) to be a significant source of predation on Mexican garter snakes (*T. eques*). Identifying sources of mortality for *T. gigas* would be useful in managing the recovery for this listed species.

We sampled 15 bullfrogs each month in late July and early August 2000, when radio-tracked giant garter snakes were seen giving birth. Nearly all frogs contained remains of one or more crawfish (*Procambarus clarkii*). Various crustaceans, insects, and other invertebrates (Isopoda, Oligochaeta, Arachnida, Anisoptera, Zygoptera, Chilopoda, Hymenoptera, Hemiptera, Corixidae, Dytiscidae, Hydrophilidae, and Notonectidae) were also recorded. We found the remains of three recently born *T. gigas* in the stomachs of two frogs; one in the July sample and two in the August sample. These frogs were among the smallest individuals sampled (270–300 g), suggesting that a wide size range of *R. catesbeiana* are capable of eating young of the year *T. gigas*. To our knowledge our results provide the first confirmation of such predation.

RANA CATESBEIANA (Bullfrog). **DIET**. Bullfrog food items have been extensively documented in the literature (Bury and Whelan 1984. U.S. Fish Wildl. Serv. Resource Publ. 155. 23 pp.; Schwalbe and Rosen 1999. Sonorensis 19:8–10; Korschgen and Baskett 1963. Herpetologica 19:89–99). A recent summary of the bullfrog's life history that included a literature review of prey items documented eight species of snakes taken as prey (Casper and Hendricks, *in press*. *In* M. J. Lannoo [ed.], Status and Conservation of U.S. Amphibians. Univ. California Press, Berkeley); however, this is the first observation of the Sonoran gopher snake *(Pituophis catenifer affinis)* as a bullfrog prey item.

During the early evening of 21 August 2001, 13 adult bullfrogs were collected by gigging at Watson Lake, Yavapai County, Arizona, USA. The frogs were placed in individual plastic bags and chilled on ice. The specimens were later transferred to a commercial freezer and euthanized. The following day the specimens were dissected and the gastrointestinal tracts removed for examination. Stomach contents consisted primarily of crayfish (*Procambarus clarkii*) and small bullfrogs. The stomach of one female bullfrog (mass 441 g; SVL 159 mm) contained an almost intact Sonoran

gopher snake. The snake was weighed and measured (mass 13.9 g; TL 365 mm). Both the frog and snake were catalogued into the herpetological collection at Arizona State University (ASU 33175 and 33178).

RANA CATESBEIANA (Bullfrog). **EFFECTS ON NATIVE ANURAN COMMUNITY**. During December 1997, I compiled a list of 14 species of anurans that used an area of Cerrado (savanna-like vegetation), on a farm (Fazenda Estrels) in Alexânia County, Goiás State, central Brazil. The area was ca. 20 ha and was composed of a mosaic of artificial and natural ponds, some dry and wet savannas (locally called "veredas"), and gallery forests. The most abundant species were the hylids *Hyla minuta* and *Scinax fuscovarius*, and the leptodactylids *Leptodactylus ocellatus* and *L. labirinthycus* that are frequently caught for food by the local inhabitants. Despite the high hunting pressures, the same community persisted in the area in 1998 and 1999.

During early 2000, a farmer introduced six female and two male bullfrogs into the area. These bullfrogs quickly proliferated, occupying all of the ponds on the farm. I observed several bullfrog egg masses at the edge of the ponds just a few weeks after their introduction, and tadpoles could be found in almost all ponds. The bullfrogs preferentially occupied recent and large artificial ponds without peripheral vegetation. Some partitioning of space was noticed, with the hylid frogs using mainly the ponds with peripheral vegetation. By December 2000, the bullfrogs had produced significant changes in the local anuran community, as the previously abundant leptodactylids, *L. ocellatus* and *L. labirinthycus* had disappeared. Food was not likely a limiting resource for these frogs as they are generalists and food resources were locally abundant.

The farming of bullfrogs is a growing activity in Brazil, but regulations and studies upon the potential effects of this activity on the native anuran communities are lacking. This note confirms the strong colonizing skills of *R. catesbeiana* and that the introduction of this exotic species can disturb local anuran communities.

I thank Manrique Prada, Antônio Sebben, and Guarino R. Colli for helpful suggestions on this manuscript.

RANA LUTEIVENTRIS (Columbia Spotted Frog). **BURROW USE**. Amphibians use burrows to conserve water and for shelter from thermal extremes, and burrowing is a common behavior in arid-dwelling amphibians (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Co. New York. 670 pp.). *Rana luteiventris* in the Great Basin Desert of the western United States overwinter primarily in undercut stream banks and spring heads (K. Hatch, pers. com.), and have been observed under rocks during the active season (Ross et al. 1999. Herpetol. Rev. 30:163; pers. obs.). Although to our knowledge, the use of burrows has not been documented in *R. luteiventris* herein we report an observation of these frogs using a small mammal burrow.

On 26 July 1999, we visited a site along Toiyabe National Forest Road 018 (Nye County, Nevada; UTM 456360E, 4298150N; 2195 m elev.) between 0810–1124 h. This site included a 300 m section of Indian Creek, and was part of a mark-recapture study of *R. luteiventris*. During the visit, we searched for frogs visually and physically (i.e., moving vegetation and other cover objects and probing possible cover areas). At 0828 h, shortly after the sun had risen enough over Black Mountain to reach the west bank of the creek, we observed three frogs (male SVL 68 mm; female SVL 45 mm; unidentified) emerge from a small mammal burrow ca. 30 cm from the edge of the water. This burrow was ca. 4 cm in diameter and appeared to be the burrow of a long-tailed vole (*Microtus longicaudus*), which is common in riparian areas of the Toiyabe Range (pers. obs.). The burrow was in the west bank of the stream, which was ca. 5 cm in height, and was in a mixed gravel and sand substrate. The riparian vegetation along this part of the creek consisted of willows (*Salix* spp.) and sedges (*Carex* spp.). Air temperature 1 cm above the entrance to the burrow was 15.6°C and the temperature of the nearest water was 8.7°C.

This study was supported by a grant from the United States Fish and Wildlife Service. All frogs were handled under a scientific collection permit from the Nevada Division of Wildlife.

RANA TEMPORARIA (European Common Frog). **ALBINO LARVAE**. Throughout the last decades numerous reports of albino amphibians or their larvae have appeared in the literature. In the Netherlands, several recent observations have been made although the phenomenon has not been reported in Flanders, Belgium, which abuts Netherlands to the south.

In 1997, 1998, 2000, and 2001 between 9 and 100 albino larvae of *Rana temporaria* were found in a small artificial pond at Hofstade, Belgium (50°59'35"N, 04°31'37"E). In 1999 no albino larvae were found; however, because of flooding at least 10–20% of the larvae were lost at an early age. All the eggs from clutches deposited in those years showed the typical black color but some larvae became gradually pale after some weeks. It is unknown if all the albino larvae originated from one or from different clutches, nor what percentage of the larvae were albino. Each year only small numbers of albino larvae were found, thus we expect they are subject to high predation rates. Albino larvae raised in aquaria with typically-colored larvae did not exhibit higher mortality or slower growth rates than normal-colored larvae. After metamorphosis froglets had pink eyes and a golden, cream-colored skin.

Submitted by **JEF NIJS**, Laboratorium voor Ecologie and Systematiek, Vrije Universiteit Brussel, Pleinlaan 2 B-1050, Brussel, Belgium (e-mail: jnijs@vub.ac.be) and **HEINZ KELLER**, Veldonkstraat 308 B-3120 Tremelo, Belgium.

XENOPUS LAEVIS (African Clawed Frog). **BEHAVIOR**. *Xenopus laevis* is frequently regarded as being totally aquatic at all stages of its life history. In both natural and introduced populations, this species has been observed to rapidly colonize isolated ponds (McCoid and Fritts 1980. Southwest. Nat. 25:272–275). Observations of adult mass migrations have been made during torrential rain (Tinsley et al. 1996. *In* Tinsley and Kobel [eds.], The Biology of *Xenopus*, pp. 35–59), and mark-recapture studies have documented movement of individual animals (Measey and Tinsley 1998. Herpetol. J. 8:23–27), but conditions under which these individual movements are made remain unknown.

On the evening of 26 September 2001, we sampled rodents in agricultural fields around Santiago, Chile (La Platina 33°34'04.2"S, 70°37'13.9"W) using Sherman traps. One trap was placed in a dry irrigation canal, and the following morning it contained a juvenile (SVL 36.4 mm) *X. laevis* (Museo Nacional de Historia Natural de Chile MNHNC-3368). A thorough inspection of the area revealed a dam, with a known population of *X. laevis* 1500 m from the capture site. From the dam, a number of irrigation canals run throughout the area. Flow is regulated by a system of gates, and the nearest ditch with standing water was 170 m from the capture site.

The use of *X. laevis* in a laboratory context has provided misleading conclusions about its natural history, especially with regard to terrestrial behavior. This finding corroborates observations of Measey and Tinsley (*op. cit.*) that individual *X. laevis* move overland. Further, we are able to add that movements are nocturnal and that animals may not be inhibited by dry conditions. This observation is important in studies of population dynamics and gene flow in this species. It is particularly important in relation to the management of invasive populations, currently known from UK, Chile, and USA.

TESTUDINES

CHRYSEMYS PICTA PICTA (Eastern Painted Turtle). **PREDATION**. On 1 August 2000 at 0900 h, I observed a northern harrier (*Circus cyaneus*) attacking a juvenile *Chrysemys picta picta* at Blandy Experimental Farm, Clarke County, Virginia, USA. The turtle was on land in a mowed clearing ca. 60 m from a drying pond. The harrier was accidentally flushed, thereby aborting the attack, by my approaching vehicle. I do not know whether the harrier would have been successful. Aside from superficial scratches on the carapace, the turtle appeared unharmed. Body mass and plastron length were 102 g and 81.2 mm, respectively. The turtle was released at point of capture. Several raptors have been reported to occasionally prey upon *C. picta* (Ernst et al. 1994. Turtles of the United States and Canada, Smithsonian Institution Press, Washington D.C. 578 pp). To my knowledge, predation by the northern harrier on *C. picta* has not been previously documented (Sherrod 1978. Raptor Res. 12:49–121).

I thank Joseph C. Mitchell for commenting on this note.

CROCODYLIA

CAIMAN LATIROSTRIS (Broad-snouted Caiman) **COURTSHIP BEHAVIOR.** The reproductive biology of the broad-snouted caiman has been studied in association with its ranching (Larriera 1988. Rev. Arg. Prod. Anim. 8:429–432) and farming (Verdade 1995. *In* Larriera and Verdade [eds.], Conservación y Manejo de los Crocodylia de America Latina. Vol. 1. Santo Tomé, Santa Fe, Argentina: Fundación Banco Bicaprograms) programs. However, little is known about its reproductive behavior.

Courtship behavior of crocodilians might be as intricate and complex as that exhibited by some birds, although not as many studies have been conducted with this group. Eight distinct behavioral components have been described for the American alligator (*Alligator mississippiensis*) (Vliet 1989. Amer. Zool. 29:1019–1031): A) elevated posture; B) head oblique tail arched posture; C) subaudible vibrations; D) headslap; E) jawclap; F) growl; G) inflated posture; and, H) tail wag. Among them, subaudible vibration has been described only for males, generally preceding headslap. Some vocalization (e.g., jawclap and growl) might also be associated with these displays. While the reproductive behavioral components are well known for the American alligator, they have never been described for the broad-snouted caiman. Although some differences are clear, some of the social displays listed above might also apply for the broad-snouted caiman, as our observations suggest.

On 23 October 2000, at 1030 h we observed the following behavior in one of the breeding groups (one male: four females) of the captive colony of *Caiman latirostris* at the University of São Paulo (22°42.557'S, 47°38.246'W) in Piracicaba, State of São Paulo, Brazil. The male (109 cm SVL), swimming slowly, approached the group of females basking at the edge of the pool. Still in the water, the male exhibited a head oblique tail arched posture (similar to B, above). He then assumed an elevated posture (similar to A, above) remaining this way for ca. 1 min. He then turned to the head oblique tail arched posture (B) and contracted his trunk slightly, shaking his head and producing a subaudible vibration (similar to C, above) that lasted for ca. 2 min. Although not a "water dance" (as described by Vliet 1989, *op. cit.*), the water sprinkling caused by vibration was visible, the 1.2 m high brick wall 2 m from him vibrated simultaneously as an effect of the caiman's subaudible vibration. The male did not produce any sound like headslap, jawclap, or growl either during or after vibrating, but the females did growl (similar to F, above) in response to him. After that, the male assumed an inflated posture (similar to G, above), but did not show any tail movement like tail wag (H). After 23 October, the head oblique tail arched posture (B) was observed in association with copulation attempts, but with neither subaudible vibration nor the other behavioral act components described by Vliet (1989, *op. cit.*).

Vocalizations in crocodilians seem to be associated with habitat (Lang 1987. *In*: Webb, Manolis, and Whitehead [eds.], Wildlife Management: Crocodiles and Alligators. Surrey Beatty, Chipping Norton, Australia). Species that inhabit vegetated areas tend to be

more vocal than species that live in open rivers. The broad-snouted caiman is essentially a palustrine and not a riverine species (Verdade and Sarkis-Gonçalves. *In press*. *In* Larriera and Verdade [eds.], Conservación y Manejo de los Crocodylia de America Latina. Vol. 2. FEALQ, Piracicaba, São Paulo, Brazil), whereas the American alligator lives in both open river and swamps. Notwithstanding, the behavior described above suggests that *Caiman latirostris* presents a less elaborate courtship and less vocal behavior than the American alligator.

Submitted by **TARSIS RODRIGO O. PIFFER** and **LUCIANO M. VERDADE***, Laboratório de Ecologia Animal / ESALQ, Universidade de São Paulo, C.P. 09 Piracicaba, SP 13418-900, Brazil. *Corresponding author.

CAIMAN LATIROSTRIS (Broad-snouted Caiman). **THERMOREGULATION.** It has been demonstrated that increasing body temperature (fever) is a common response to infection among crocodilians (Lang 1987. *In* G. J. W. Weeb, C. Manolis and P. J. Whitehead [eds.], Wildlife Management: Crocodiles and Alligators, Surrey Beatty and Sons, Chipping Norton, New South Wales. 552 pp.). Deakins (1980. *In* J. B. Murphy and J. T. Collins [eds.], Reproductive Biology and Diseases of Captive Reptiles, SSAR, Lawrence, Kansas. 277 pp.) reported that parasitic infections in snakes can be treated by increasing environmental temperature. On the other hand, decreasing temperatures often exacerbates viral and bacterial infections, making reptiles more susceptible to disease (Marcus 1980. *In* Murphy and Collins, *op cit.*). This is the first report of fever behavior in *Caiman latirostris*.

Observations were made at the breeding facility of "Granja la Esmeralda," Santa Fe, Argentina, a naturalistic facility comprised of large ponds enclosed by fence. The facility is operated for educational and research purposes (not production), so animal densities are kept low. At the beginning of the breeding season for broad-snouted caimans in Santa Fe (31°42'S, 60°44'W; December through March), females and males struggle for a suitable place in the breeding pool. In December 1997, a young female (ca. 1.5 m) sustained an injury to her back and legs while fighting with a larger female. After the fight, the young female behaved normally, but two days later colleagues and I observed that the caiman's wounds were inflamed and showed signs of infection and, later, necrosis. At this point, she increased the time spent basking. At noon and early evening, when the other animals in the enclosure were in shaded water, she was observed basking; this behavior is consistent with fever behavior as reported by Lang (1987, *op. cit.*). She basked continuously, including the hottest part of the day (ca. 1600 h). Body temperature was not measured, but temperature of water and shade in the pool was recorded during the breeding season with two calibrated Hobo Temp Data Loggers (Onset Computer Corp., Pocasset, Massachusetts, USA). Average temperatures were: 25.8°C (water) and 24.8°C (air). Temperature differences between shade and sun averaged 10°C during the day. Lang (1987, *op. cit.*) reported that the mean difference in body temperature between infected animals and controls (mean of 30.1°C) was 4.9°C with a maximum difference of 7.4°C. The young female of this report continued her heat-seeking behavior for 10 days and then reassumed typical behavior, acting similar to the rest of the animals of the enclosure.

I thank M. R. Cabrera and G. Scrocchi for their comments and suggestions on the manuscript.

Submitted by **CARLOS I. PIÑA**, Proyecto Yacaré, CIC y TTP-CONICET, Dr. Matteri y España, CP 3105, Diamante, Entre Ríos, Argentina; e-mail: cidcarlos@infoshopdte.com.ar.

LACERTILIA

CYCLURA NUBILA NUBILA (Cuban Iguana). **CARRION FEEDING**. West Indian iguanas of the genus *Cyclura* feed almost exclusively on vegetation (Alberts [ed.] 2000. West Indian Iguanas: Status Survey and Conservation Action Plan. IUCN, Gland, Switzerland. 111 pp.; Auffenberg 1982. *In* Rand and Burghardt [eds.], Iguanas of the World: Their Behavior, Ecology, and Conservation. Noyes Publications, Park Ridge, New Jersey. 472 pp.; Wiewandt 1977. Ecology, Behavior, and Management of the Mona Island Ground Iguana, *Cyclura stejnegeri*. Unpublished Doctoral Dissertation, Cornell University. 338 pp.). Animal matter typically constitutes less than 5% of the diet of *Cyclura*, consisting primarily of slow moving arthropods, such as lepidopteran larvae, and other prey that are easily captured (e.g., Wiewandt 1977, *op. cit.*). Predation of vertebrates is not known in *Cyclura*, but feeding on vertebrate carrion (fish and birds) has been described for *C. carinata carinata* in the Turks and Caicos Islands (Iverson 1979. Bull. Florida State Mus., Biol. Sci. 24:175–358). Here, we report observations of vertebrate carrion feeding for *C. nubila nubila* at the United States Naval Base at Guantanamo Bay, Cuba.

At 1030 h on 23 July 2000, three of us (GPG, TDG, and ACA) observed an adult female *C. n. nubila* (ca. 35 cm SVL) crossing the Ridgeline Trail Road carrying a dead bird in its jaws (Fig. 1). The iguana was followed and observed for fifteen minutes. During this time, the iguana stopped several times to feed on the carcass. Each time, the iguana grasped the bird in the edge of its jaws and shook its head to tear loose some feathers and presumably flesh, which were swallowed. After the fourth such feeding bout, the iguana was chased away before it could pick up the bird again so that the carcass could be examined and identified. The bird was identified by one of us (MAH) as a nestling mourning dove, *Zenaida macroura*. Due to the condition and odor of the carcass, it was clear that the bird had been dead for at least a day. Iverson

FIG. 1. Adult female *Cyclura nubila nubila* with a dead *Zenaida macroura* in its jaws.

(1979, *op. cit.*) describes *C. c. carinata* being attracted to carrion by odor, and this might be the case for *C. n. nubila* as well.

On another occasion, while monitoring active bird nests at the Naval Base, one of us (MAH) observed an iguana scavenging on the decaying remains of a nestling white-winged dove, *Z. asiatica*, which had fallen out of its nest and died several days prior. In addition, researchers using mist nets to capture birds for a banding study at the Naval Base reported observations to us suggesting that iguanas might occasionally take small birds, such as Cuban grassquits (*Tiaris canora*), captured in nets.

These observations of *C. n. nubila*, combined with reports by Iverson (1979, *op. cit.*) for *C. c. carinata*, suggest that probably all *Cyclura* are opportunistic scavengers of vertebrate remains. In contrast, there is no evidence that *Cyclura* prey on living vertebrates under natural conditions. In fact, some *Cyclura* populations co-occur with dense concentrations of breeding seabirds: e.g., *C. c. carinata* with bridled terns (*Sterna anaethetus*) and brown noddys (*Anous stolidus*) on small cays in the Turks and Caicos Islands, and *C. n. caymanensis* with red-footed boobys (*Sula sula*) and magnificent frigatebirds (*Fregata magnificens*) on Little Cayman Island. There is no indication that iguanas actively prey on the eggs or nestlings of these birds (GPG, pers. obs.).

EUMECES BREVIROSTRIS (Short-nosed Skink). **REPRODUCTION.** *Eumeces brevirostris* is a montane skink that is widely distributed in Mexico (Flores-Villela 1993. Herpetofauna Mexicana. Annotated List of the Species of Amphibians and Reptiles of Mexico, Recent Taxonomic Changes, and New Species. Special Publication No. 17, Carnegie Museum of Natural History. 73 pp.). Reports that *E. brevirostris* is viviparous are summarized in Blackburn (1993. Herpetologica 49:118–132). The purpose of this note is to provide information on the reproductive cycle from a histological examination of reproductive tissue from museum specimens.

Thirty-six *E. brevirostris* were examined: six from the Natural History Museum of Los Angeles County (LACM), 20 from the University of Arizona (UAZ), and 10 from the Field Museum of Natural History (FMNH). The sample consisted of 18 males, mean SVL = 55 mm ± 6 SD, range = 46–64 mm; 16 females, mean SVL = 56 mm ± 5 SD, range = 49–66 mm, and two neonates. Lizards were collected 1938–1979. Specimens were from the Mexican states of Durango, Guerrero, Nuevo Leon, and Puebla. The posterior portion of the body cavity was opened and the left gonad was removed for histological examination except for enlarged, yolked follicles (> 5 mm diameter) or oviductal eggs, which were measured with calipers. Tissues were embedded in paraffin and sections were cut at 5 µm. Slides were stained with Harris hematoxylin followed by eosin counterstain.

Male Cycle: June (N = 6), three males in spermiogenesis, three in late recrudescence with metamorphosing spermatids but no sperm; July (N = 2), late recrudescence with metamorphosing spermatids but no sperm; August (N = 9) all in spermiogenesis; September (N = 1) spermiogenesis. Minimum size for reproductive activity (spermiogenesis) was 46 mm SVL.

Female Cycle: March (N = 1) two enlarged follicles 5 mm length; April (N = 2) one with five oviductal eggs from 9 April; one with three oviductal eggs from 9 April; June (N = 4) one with two well developed embryos from 5 June; three with no yolk deposition which may have already given birth; July (N = 1) no yolk deposition; August (N = 8) six with no yolk deposition, two with early yolk deposition. Minimum size for reproductive activity (eggs 5 mm length) was 49 mm SVL. Two neonates were collected in June: 19 June SVL = 23 mm; 27 June SVL = 21 mm.

The reproductive cycle of *E. brevirostris* seems similar to that of another high-elevation, viviparous Mexican skink, *E. copei*, which was studied by Guillette (1983. J. Herpetol. 17:144–148) and Ramirez-Bautista et al. (1996. Southwest. Nat. 41:103–110). In *E. copei*, males have maximum testicular volumes in spring and summer; females begin vitellogenesis in August, ovulate in late autumn, and births occur between May and July (Ramirez-Bautista et al., *op. cit.*). The timing of events in the *E. brevirostris* reproductive cycle appear similar.

I thank David A. Kizirian (Natural History Museum of Los Angeles County), Charles H. Lowe (University of Arizona), and Alan Resetar (Field Museum of Natural History) for permission to examine *E. brevirostris*.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA; e-mail: SGoldberg@whittier.edu.

EUMECES LATICEPS (Broad-headed Skink) **DIET.** On 11 September 1997 in Morehouse Parish, Louisiana, USA (32°47'N, 91°52'W) we observed a female *Eumeces laticeps* eating from a peeled banana. Vitt and Cooper (1986. J. Hepertol. 20:408–415) reported finding no plant material in 84 stomachs of *E. laticeps*, but they had observed *E. laticeps* eating muscadine grapes and blackberries, both in the field (Cooper, pers. comm. to GP in 1998). In 1998 we observed a male *E. laticeps* eating a mixture of food, prepared for box turtles, the primary ingredients of which were ground carrots and lean ground beef, oat bran, and Knox® gelatin.

We thank William E. Cooper, Jr. for his help.

FURCIFER OUSTALETI (Oustalet's Chameleon). **DIET.** *Furcifer oustaleti* is one of the largest chameleons of Madagascar; adult males can reach 68.5 cm TL (Brygoo 1971. Faune de Madagascar 33:1–318). Chameleons generally catch their prey using their long, protusible tongue. Because of this mechanism, prey mostly consists of invertebrates (Davison 1997. Chameleons: Their Care and Breeding. Hancock House Publishers, Blaine, Washington. 118 pp.). Mammals (mice) and small birds have also been noted as potential prey (Necas 1999. Chamäleons - Bunte Juwelen der Natur. Chimaira, Frankfurt. 249 pp.), but to our knowledge there have been no reports of Malagasy chameleons preying on

FIG. 1. Adult male *Furcifer oustaleti* carrying a bird in its jaws at Ampijoroa Forest Station.

birds. On 23 May 2000 at ca. 1600 h, one of us (GG) observed an adult male *F. oustaleti* at Ampijoroa Forest Station (16°20'S, 46°47'E, elev. ca. 70 m) on a shrub branch at ca. 2 m height. The lizard was carrying a dead bird in his mouth (possibly a young *Foudia madagascariensis*) (Fig. 1). During the observations (ca. 30 min), the chameleon moved along the branch without leaving its prey, and finally swallowed it completely. The bird was not a hatchling (as recognizable by its well-developed feathers), and therefore almost certainly was not captured in a nest.

GECKOLEPIS MACULATA (Spotted Fishscale Gecko). **PREDATION**. Few cases of scorpions preying on lizards have been reported: *Centruroides exilicauda* preying on *Phyllodactylus* sp., *Hadrurus arizonensis* on *Cnemidophorus* sp., *Parabuthus villosus* on *Palmatogecko rangei*, and *Opistophthalmus carinatus* on *Pachydactylus capensis* and *Mabuya striata* (McCormick and Polis 1990. *In* Polis [ed.], The Biology of Scorpions. Stanford Univ. Press, Stanford, California. 587 pp.). The first two examples concern species from North America and the other two from South Africa. No data concerning scorpions preying on Malagasy lizards are available. On 14 March 2000 we observed a scorpion eating a subadult specimen of *Geckolepis* at Montagne des Français, northern Madagascar (12°19'34"S, 49°20'09"E, 335 m elev.). The specimens were found during the day under a stone in degraded dry forest. The *Geckolepis* (SVL ca. 33 mm) had already been partly consumed (tail, left hindleg, and part of digestive tract); it was preserved and deposited in the Zoologische Staatssammlung München (ZSM 527/2000). *Geckolepis* systematics are in need of revision; according to the meristic characters used for species diagnosis in the genus (Angel 1942, Les lezards de Madagascar, Mem. Acad. Malgache 36. 139 pp.), the specimen was determined as *G. maculata*. The scorpion was an adult male *Grosphus flavopiceus* with a total length of 85 mm, including the telson; it was deposited at the Muséum national d'Histoire naturelle (MNHN-RS-8539). *Grosphus flavopiceus* is known from Montagne des Français (Lourenço 1996, Scorpions [Chelicerata, Scorpiones], Faune de Madagascar 87. 102 pp.); it lives almost exclusively in dry areas (Lourenço and Cloudsley-Thompson 1998, Biogeographica 74:183–187) and is an active predator of prey with rapid movements, similar to most scorpion species from deserts or dry areas.

HELODERMA SUSPECTUM (Gila Monster). **MORTALITY/PREDATION**? Little is known about potential predators of the venomous Gila monster, but they are suspected to be few (Bogert and Del Campo, 1956. Bull. Amer. Mus. Nat. Hist. 109:1–238). As part of a study of the activity of Gila monsters in the Sonoran Desert near Phoenix, we observed the apparent outcome of a predation event involving a male Gila monster and a mammalian carnivore.

An adult male Gila monster, 250 mm SVL (294 g), was initially captured in northern Phoenix, Arizona, on 12 April 2000, surgically implanted with a small radio-transmitter (12 g), and released (1600 m from its capture site) in typical Upland Sonoran Desert dominated by creosote bush, bursage, palo verde, and saguaro cacti. It was relocated once or twice a week over the next fifteen months, during which time it grew 19 mm in length and 26 g in mass. On 27 June 2001 we radio-tracked the male Gila monster, and located the exposed tag and the head and neck of the lizard. The tag was exceptionally clean and exhibited small indentations consistent with the bite marks of a canid or similar-sized carnivore. The tag was imbedded in dry grasses over which an animal had apparently rolled repeatedly. Approximately 10 m from the tag the head and neck of the Gila monster were found with evidence that tissue had been "stripped" from the ribs and vertebral column. The lizard had been radio-tracked on 23 June 2001; at that time it was in a pack rat nest approximately 125 m from the subsequent location of the tag and head.

Although we have no direct evidence, we think that a coyote is the most likely candidate as the predator responsible for killing and consuming the Gila monster. Firstly, other carnivores (e.g., feral dogs, kit or grey foxes, skunks, badgers) have not been observed at the site, which is entirely surrounded by urbanization, over the past two years; coyotes are commonly observed at the site. Secondly, the radio tag was exceptionally clean (as if mouthed repeatedly) and apparently "rolled on," behaviors commonly exhibited by canid predators. Lastly, given the short time that had elapsed since its previous location in a traditional refuge, it seems unlikely that the Gila monster died of some other cause and subsequently was fed upon (as carrion) by a coyote.

This work was supported by a Heritage Fund Grant from the Arizona Game and Fish Department.

TROPIDURUS MONTANUS (NCN). **CANNIBALISM.** Cannibalism is a common occurrence among reptiles (Polis and Myers 1985. J. Herpetol. 19:99–107) and has been recorded in several lizard species (e.g., Polis and Myers, *op. cit.*; Rocha 1992. Herpetol. Rev. 23:60; Vrcibradic and Rocha 1997. Herpetol. Rev. 27:201–203; Zamprogno and Teixeira 1998. Herpetol. Rev. 29:41–42). Here we report a case of cannibalism in the Brazilian endemic, sit-and-wait tropidurid *Tropidurus montanus* from the Serra do Cipó (19°20'S, 43°44'W), Minas Gerais, in the Espinhaço Range in southeastern Brazil.

Stomach contents of 133 adult lizards collected during the dry (June–August) and wet (December–February) seasons of 1996/1997 were analyzed. One adult male (76.6 mm SVL, 14.5 g), collected in August, had a partly digested juvenile conspecific in its stomach. The juvenile lacked a head and middle of the body, and its tail was broken. Morphological comparison with other specimens of the same population indicates the juvenile was ca. 40 mm SVL. Several ants, wasps, and a grasshopper, all food items common in the diet of *T. montanus* (Kiefer 1998. Unpubl. Master's Thesis, Universidade Estadual Paulista, Rio Claro, São Paulo, Brazil. 92 pp.), were also found in the examined stomach. The relatively low incidence of cannibalism (0.7%) recorded for the studied population of *T. montanus*, and its occurrence in the dry season when there is a great number of juveniles in the population and the availability of arthropods is lower, may suggest that cannibalism is a consequence of opportunistic foraging. Thus, conspecific juveniles would be treated as another prey available for adults (Polis and Myers, *op. cit.*). Opportunistic predation on lizards other than conspecifics has been reported for *T. montamus* (Kiefer 1998. Herpetol Rev. 29:41). The two specimens (predator and prey) were deposited in the herpetological collection of the Museu de História Natural da Universidade Estadual de Campinas (ZUEC 02283 and 02284, respectively).

We thank C. F. D. Rocha and M. Van Sluys for reading an earlier version of the manuscript, the CAPES for a fellowship grant at the Universidade Estadual Paulista (Unesp, Rio Claro) to MCK, and the CNPq for a grant to IS.

SERPENTES

AGKISTRODON PISCIVORUS (Cottonmouth). **PREDATION.** *Agkistrodon piscivorus* is a generalist forager that consumes live prey and carrion (Gloyd and Conant 1990. Snakes of The *Agkistrodon* Complex: A Monographic Review. SSAR, Oxford, Ohio. 614 pp.; Greene 1997. Snakes: The Evolution of Mystery in Nature. University of California Press, Berkeley, California. 351 pp.). Dietary plasticity in *A. piscivorus* might be a consequence of the snake's use of various aquatic and semi-aquatic environments (Ernst 1992. Venomous Reptiles of North America. Smithsonian Inst. Press, Washington D.C. 236 pp.). Although several species of terrestrial and aquatic birds have been reported eaten by *A. piscivorus*, consumption of wood duck (*Aix sponsa*, Anseriformes) ducklings by this snake is unknown (Gloyd and Conant, *op. cit.*). This seems unusual because ranges of *A. sponsa* and *A. piscivorus* greatly overlap in southern United States (Bellrose 1980. Ducks, Geese, and Swans of North America. Stackpole Books, Mechanicsburg, Pennsylvania. 540 pp.).

I studied survival, habitat use, and causes of mortality of radiomarked *A. sponsa* ducklings in three unique wetland environments at Noxubee National Wildlife Refuge (NNWR) in east-central Mississippi, USA (1996–1999) and in a riverine system of the Tennessee-Tombigbee River Waterway (TTRW) in western Alabama, USA (1998–1999). At NNWR, I studied in Loakfoma Lake (243 ha); the lake contained willow (*Salix nigra*), buttonbush (*Cephalanthus occidentalis*), and a variety of herbaceous species. Mosaics of vegetation were often dense and interspersed along Loakfoma's shoreline and islands. My second study site at NNWR was a reservoir (Bluff Lake, 405 ha), a needle-leaved deciduous forested wetland dominated by bald cypress (*Taxodium distichum*) and interspersed emergent herbaceous vegetation. The third site at NNWR was bottomland hardwood forest adjacent to Loakfoma and Bluff Lakes. At TTRW, I studied at Aliceville Lake (3320 ha) near Pickensville, Alabama, USA. The lake consisted of a navigation channel and numerous backwater coves remaining from the Tombigbee River. Coves at TTRW contained various aquatic macrophytes and were generally bordered by patches of dense emergent herbaceous vegetation adjacent to forest or oldfield upland habitats.

I captured *A. sponsa* ducklings and the brooding female in nest boxes and fitted birds with radio transmitters. Three ducklings per brood were usually marked. I attempted to radiomark equal numbers of ducklings through time at both study areas in 1998 and 1999 to control for temporal variation in duckling survival. I tracked radiomarked ducklings daily. Snakes suspected of ingesting radiomarked ducklings were captured with tongs to verify species, and to note their size and appearance. I released snakes alive at the capture site and recorded their location at time of capture.

I used program MICROMORT (Heisey 1985. MICROMORT version 1.2. Minn. Dept. of Natur. Resour., Minneapolis, Minnesota, USA) to calculate cause-specific mortality rates of ducklings, and to estimate the importance of predation of ducklings by *A. piscivorus* relative to other predators. *A. piscivorus* consumed a total of 21 radiomarked *A. sponsa* ducklings at both sites during 1996–1999. Intraseasonally (1999), one snake ingested 2 and another snake ingested 3 radiomarked ducklings. The other snakes each consumed 1 radiomarked duckling; I based this on size, color

characteristics, and location of the snakes captured. No radiomarked brood-rearing hens (N = 135) were killed by snakes. *A. piscivorus*-specific predation rates of ducklings relative to other agents of duckling mortality across years and study areas ranged from 0 to 15.9% (0.076 ± SE). *A. piscivorus*-related duckling mortality annually ranked from zero to 3rd in importance among other mortality agents. Most (16 of 21) radiomarked ducklings were eaten by *A. piscivorus* in Loakfoma Lake; 2 and 3 ducklings were consumed by snakes in Bluff Lake and TTRW, respectively. No ducklings were consumed by *A. piscivorus* in bottomland hardwood forest. Ducklings averaged 7.2 d of age (range 1–18 d) when consumed by snakes. Water levels at duckling predation sites (n = 14) averaged 29 cm (range 7.0-48.3 cm) among wetlands. No other species of snake consumed radiomarked wood duck ducklings in this study although four species of *Nerodia* were present on the study areas (Lohoefener and Altig 1981. Miss. Herpetol. Miss. State Univ. Res. Bull. 1).

Agkistrodon piscivorus ingested *Axis sponsa* ducklings in 3 of 4 wetland environments at the two study areas. However, snakes ate the greatest proportion of ducklings in Loakfoma Lake, usually among dense patches (i.e., nearly complete coverage of water) of interspersed *C. occidentalis* and herbaceous emergent vegetation that were flooded ≤ 29 cm deep. Although several factors may have influenced the observed pattern of consumption of ducklings by *A. piscivorus* in Loakfoma Lake, scrub-shrub habitats (e.g., *C. occidentalis*) are favorable habitats for *A. sponsa* (Bellrose and Holm 1994. Ecology and Management of The Wood Duck. Wildlife Management Institute. Stackpole Books, Mechanicsburg, Pennsylvania. 588 pp.) and seem to be favorable resting and foraging areas for *A. piscivorus*. *A. piscivorus* may be important predators of *A. sponsa* ducklings during simultaneous spatio-temporal use of some wetland environments in southern United States.

ATRACTUS PANTOSTICTUS (Fura-terra). **CLUTCH SIZE.** Colubrid snakes of the genus *Atractus* are oviparous, produce clutches of about 3 eggs and are fossorial (Amaral 1978. Serpentes do Brasil: Iconografia Colorida. 2ª ed. São Paulo, Edusp. 248 pp.; Fernandes and Puorto 1993. Mem. Inst. Butantan 55:7–14; Martins. 1994. História Natural e Ecologia de uma Taxocenose de Serpentes de Mata na Região de Manaus, Amazônia Central, Brasil. Ph.D. dissertation. Univ. Estadual de Campinas, São Paulo, Brazil. 98 pp.). Their fossorial habits make data gathering difficult. There are no data on oviposition by *A. pantostictus* except for one laboratory record of a female that deposited four eggs (mean length = 36.7 mm, mean weight = 1.88 g) (Fernandes and Puorto, *op. cit.*). Herein we report the clutch size of one female of *A. pantostictus* found in Belo Horizonte, Minas Gerais, Brazil.

A female collected on 4 March 1999 near Belo Horizonte (19°55'S, 43°56'W) laid in captivity three ellipsoid eggs (mean length = 32.0 mm, mean width = 7.5 mm, mean weight = 1.05 g) on 5 March 1999. Oviposition behavior was not observed. Measurements of the female following oviposition were: 9.5 g., 290.0 mm SVL, and 35.4 mm tail length. The clutch mass/female mass ratio was 0.33. The eggs did not hatch.

The adult female and eggs were deposited in the herpetological collection of the Universidade Federal de Minas Gerais (UFMG - 322).

We thank Vinícius Xavier and Claudia Jacobi for comments and improvements on the manuscript.

Submitted by **JOSÉ CASSIMIRO, JAIME BERTOLUCI**, and **WALDNEY PEREIRA MARTINS**, Departamento de Zoologia, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, 31270-901, Belo Horizonte, Minas Gerais, Brazil (e-mail [JC]: j_cassimiro@hotmail.com).

BITIS CAUDALIS (Horned Adder). **PREY SIZE.** On 27 May 2000 we collected a small horned adder (*Bitis caudalis*) (CAS 214559) at the base of a small shrub in coastal gravel plains east of Henties Bay, Swakopmund District, northern Namibia (22°06'15"S, 14°17'27"E). The specimen contained a large Carp's barking gecko (*Ptenopus carpi*) in its stomach (Fig. 1). Measurements for the snake were: 130.42 mm SVL, 10.01 mm tail length, 7.12 mm head width, 10.22 mm head length, 10.06 mm maximum body width; weight (preserved, drained and patted dry) 2.02 g. The prey, an adult female gecko, had been ingested headfirst and was intact except for slight digestion of the skin anterior to the eyes. The gecko measured 51.55 mm SVL, 33.56 mm tail length, and weighed 3.17 g (preserved, patted dry). The relative prey mass (RPM; prey mass/snake mass) was 1.57. The intact state of the prey item suggests that it had been ingested the previous evening when conditions were cold (11–13°C) and foggy and large numbers of *P. carpi* were active on the surface at nearby localities.

Shine et al. (1998. Copeia 1998:391–401) noted that most horned adder prey items are relatively small, and that the relative prey mass is greatest in small snakes. The largest RPM they recorded for the species, 0.73, involved a juvenile snake (<170 mm SVL). Horned adders are generally born in the southern summer (December–February) at total lengths of 130–140 mm (Broadley 1990. FitzSimons' Snakes of Southern Africa. Jonathan Ball and Ad. Donker Publ., Parklands, South Africa. 387 pp.) and it is certain that the small adder involved in this case was in its first postnatal season. This record substantiates Haacke's (1975. Ann. Transvaal Mus. 29:197–243, pls. 10–11) listing of *Bitis caudalis* as a potential predator of *Ptenopus carpi*.

FIG. 1. Juvenile *Bitis caudalis* (CAS 214559) weighing 2.02 g and its prey, a *Ptenopus carpi* weighing 3.17 g. Total length of snake = 140.43 mm. The skin of the snake's body is distended because the specimen was fixed prior to removal of the prey item. Photo by Dong Lin, California Academy of Sciences.

Viperids in general often take exceptionally large prey, but data are lacking for most viperines (Greene 1983. Amer. Zool. 23:431–441). Among the greatest relative prey masses recorded from crotaline vipers are 1.29 for a hognosed pitviper (*Porthidium nasutum*) feeding on a spiny pocket mouse (*Heteromys desmarestianus*)(Greene 1997. Snakes. The Evolution of Mystery in Nature. University of California Press, Berkeley, California. 351 pp.), 1.30 for juvenile jararacas (*Bothrops jararaca*; prey item not stated)(Sazima 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 199–216. Selva, Tyler, Texas), and 1.56 for a *Bothrops atrox* that had ingested a *Cnemidophorus gramivagus* (Greene 1983, *op. cit.*, 1992. *In* Campbell and Brodie [eds.], Biology of the Pitvipers, pp. 107–117. Selva, Tyler, Texas). The last record is comparable to our own and, like ours, is subject to some error because weights were taken from preserved material (H. W. Greene, pers. comm..).

This new relative prey size record far surpasses any other known for the horned adder or for any other viperine; it also appears to represent the relatively largest meal ever recorded for any snake species.

BAUER**, Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA (e-mail: aaron.bauer@villanova.edu), and **TRIP LAMB**, Department of Biology, East Carolina University, Greenville, North Carolina 27858, USA (e-mail: lamba@mail.ecu.edu).

COLUBER RHODORACHIS (Wadi/Cliff Racer). **DIET**. *Coluber rhodorachis* is one of the commonest snakes encountered in the Hajar Mountains, especially in wadis, in the eastern United Arab Emirates and northeastern Sultanate of Oman. Although *C. rhodorachis* feeds mainly on lizards (Leviton et al. 1992. Handbook to Middle East Amphibians and Reptiles. Society for the Study of Amphibians and Reptiles. 252 pp.), records of fish (fresh and saltwater), toads, rodents, other reptiles and even bats are also included in the diet (Gallagher 1993. Snakes of the Arabian Gulf and Oman, Mazoon Printing Press, Oman. 16 pp.; Jongbloed 2000. Wild about Reptiles, Barkers Trident Communications, London. 116 pp.). During December 2000, I witnesses an adult *C. rhodorachis* preying on *Bufo arabicus* tadpoles in an ephemeral pool in Wadi Shawayah, in the Hatta (UAE/Sultanate of Oman) border area. Although *Bufo dhufarensis* toads also occur in the area, identification of the tadpoles in the pool confirmed *B. arabicus* as the prey species. It is expected that *C. rhodorachis* also prey upon *B. dhofarensis* although not witnessed here, or documented previously. I have also seen the freshwater fish, *Garra barreimiae* (a cyprinid endemic to the Hajar Mountains) and *Aphanius dispar* (Arabian killifish, a euryhaline cyprinodont) preyed on by *C.rhodorachis* in similar habitats. Although it could be expected that tadpoles fall prey to *C. rhodorachis* I believe this is the first record of *B. arabicus* tadpoles in the diet of *C.rhodorachis*.

Submitted by **PETER LOW CUNNINGHAM**, P.O. Box 17258, Al Ain, United Arab Emirates; e-mail: plc@emirates.net.ae.

CROTALUS CERASTES (Sidewinder). **ENDOPARASITES.** *Crotalus cerastes* has previously been reported to harbor two species of nematodes, *Thubunaea cnemidophorus* and *Hexametra boddaertii* (Babero and Emmerson 1974. J. Parasitol. 60:595; Bursey et al. 1995. J. Helminthol. Soc. Washington 62:78–80). The purpose of this note is to report an additional endoparasite, larvae of spiny-headed worms (Acanthocephala). Eight *C. cerastes* collected in Pima County, Arizona, USA, and accessioned in the herpetology collection of the Natural History Museum of Los Angeles County (LACM) were examined. A mid-ventral incision was made in the body wall, and organ surfaces and mesenteries in the posterior portion of the body cavity were visually checked for endoparasites. Oblong whitish bodies, ca. 1 x 3 mm were seen in LACM 76338 and 115995. These bodies proved, upon microscopic examination, to be oligacanthorhynchid acanthocephalan cystacanths. Prevalence of infection (infected snakes/sample examined x 100) was 25%. Parasite voucher specimens were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as USNPC 91080.

Oligacanthorhynchid cystacanths have been reported from other North American viperids: *Crotalus atrox, C. lepidus, C. mitchellii, C. scutulatus, C. tigris, C. viridis,* and *C. willardi* (Bolette 1997a. J. Parasitol. 83:751-752; Bolette 1997b. Southwest. Nat. 42:232–236; Bolette 1998. J. Helminthol. Soc. Washington 65:105–107; Goldberg and Bursey 1999. Herpetol. Rev. 30:44-45; Goldberg and Bursey 2000. Herpetol. Rev. 31:104). Rattlesnakes serve as paratenic (transport) hosts for oligacanthorhynchid cystacanths (Bolette 1997b, *op. cit.*). Development to the adult form occurs when the snake is eaten by a carnivore (definitive host) (Matthews 1998. An Introduction to Parasitology. Cambridge University Press, UK. 192 pp).

We thank David A. Kizirian (Natural History Museum of Los Angeles County) for permission to examine *C. cerastes*.

CROTALUS DURISSUS (Neotropical Rattlesnake). **PREDATION.** Several studies on ocelot (*Leopardus pardalis*) feeding habits show that this cat feeds primarily on small to medium-sized terrestrial mammals, however reptiles can also be important components of their diet (Konecny 1989. *In* Redford and Eisenberg [eds.], Advances in Neotropical Mammalogy, pp. 243–264. Sandhill Crane Press, Gainesville, Florida). Snakes most often eaten by ocelots are colubrids (e.g., Ludlow and Sunquist 1987. Nat. Geogr. Res. 3:447–461).

On 5 May 2000, I collected an ocelot scat sample at Parque Estadual Morro do Diabo (22°30'S, 52°20'W), São Paulo state, southeastern Brazil, containing the remains (four distal rattle segments, and ventral and dorsal scales) of *Crotalus durissus*. The size of the scales indicates that the snake was an adult. *Crotalus durissus* is an extremely venomous and common species, found throughout the ocelot's geographic range, but has not been reported in the diet of ocelots. It is not possible to determine if the rattlesnake was consumed as prey or taken as carrion, but there is little

evidence that the ocelot is a scavenger. On the other hand, it is likely that the ocelot preyed on the rattlesnake, as other carnivorous species, such as the crab-eating fox (*Cerdocyon thous*), are known to consume venomous species (Sunquist et al. 1989. *In* Redford and Eisenberg [eds.], Advances in Neotropical Mammalogy, pp. 197-232. Sandhill Crane Press, Gainesville, Florida).

I thank Ricardo Janini Sawaya for comments, and CNPq for grants.

CROTALUS HORRIDUS (Timber Rattlesnake). **CAVE USE.** During the summer of 1999, we surveyed 90 small caves in the Ozark National Forest in Crawford County, Arkansas, USA (35°43'N, 94°28'W). During these surveys, we found *Crotalus horridus* occupying locations within or beyond the twilight zone at four sites. Individual snakes were located an average of 11.5 ± 1.50 m into the caves (range 7.5 –16. 2 m, Table 1). In two of these sites, the snakes were present for at least one week, and were found at greater distances in the cave on the second visit (Table 1).

All of these snakes were found in caves between 30 July and 28 August, although some might have been present previously because the caves had not been surveyed since May. July and August are generally the hottest and driest months of the year in the Ozarks. During August 1999, temperatures ranged from 12.9° to 39.2°C, and mean temperature during the month of August was 26.9°C (Anonymous 1999. NOAA Natl. Clim. Data, Arkansas, 15 pp.). Air temperatures near the snakes in the caves ranged from 17.6° to 20.7°C, with a mean of 19.2°C ± 0.62 (Table 1). In addition, this period was very dry; significant precipitation had not fallen since 11 July. All of the snakes were found inside the caves at locations where the cave floor was still moist. On the night of 26 August, 2.0 cm of rain fell in the area, and on a subsequent visit only one snake remained in the cave in which it had been found.

We suggest that these snakes were probably occupying the caves in order to thermoregulate and maintain water balance. All of these snakes were small (< 0.7 m) and exhibited low body mass compared to others seen outside the caves during the same period. Smaller snakes change body temperature more rapidly and lose water more quickly because of larger surface area per unit volume than do larger snakes (Bentley 1976. *In* Gans and Pough [ed.], Biology of the Reptilia, Vol. 5, pp. 365–412. Academic Press, New York). Therefore, these smaller sized *C. horridus* may have been using the caves to reduce water loss because of the hot, dry condition outside the caves. Increased exposure to hot, dry environmental conditions can be stressful for reptiles (Huey 1982. *In* Gans and Pough [ed.], Biology of the Reptilia, Vol. 12, pp. 25–91. Academic Press, New York), therefore, cooler and wetter conditions in caves might provide temporary relief until favorable conditions exist for feeding and breeding.

TABLE 1. Distances at which *Crotalus horridus* were located from cave entrances during summer of 1999.

Cave Number*	Date	Distance from entrance (m)	Cave Air Temp. (°C)
CW2363	30 Jul	16.2	17.6
CW2336	04 Aug	10.5	19.9
CW2337	16 Aug	7.5	20.7
CW2337	22 Aug	15.0	19.8
CW2360	22 Aug	7.5	17.8
CW2360	28 Aug	12.0	—

* denotes U.S. Forest Service number.

All but one *C. horridus* encountered in the caves were found in coiled position and were alert to our presence. The one exception, a snake in cave CW2363, appeared to be stalking a small woodrat (*Neotoma floridana*) that was apparently dying after being bitten. Woodrats and other small rodents were commonly seen during our surveys in these caves. Other studies have determined that small rodents comprise the majority of prey items for *C. horridus* (Savage 1967. Copeia 1967:226–227; Reinert et al. 1984. Copeia 1984:976–981), so it is possible that these snakes were occupying caves to search for prey as well as to escape the heat.

To our knowledge, there has been only one report of this species using caves outside of hibernation, a single adult found near the entrance of a cave in Oklahoma (Black 1973. Proc. Oklahoma Acad. Sci. 53:33–37). In general, pitvipers are considered accidental visitors to areas inside caves in the Ozarks (Drda 1968. J. Herpetol. 1:64–70; Black, *op. cit.*; McDaniel and Gardner 1977. Proc. Arkansas Acad. Sci. 31:68–71). Summer surveys, especially at smaller and less frequently visited sites, may produce more records of *C. horridus* in underground locations.

CROTALUS LEPIDUS MACULOSUS (Durangan Rock Rattlesnake). **DIET**. Little published data exist on the natural history of *Crotalus lepidus maculosus* and no prey items have been recorded for this subspecies. Armstrong and Murphy (1979. The Natural History of Mexican Rattlesnakes. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 5:1–88) stated that lizards of the genus *Sceloporus* appear to be the main food item of *C. l. maculosus*, presumably based on the association of these lizards with *C. l. maculosus* habitat.

From 28 June 2000 to 1 July 2000 we obtained dietary records for three *C. l. maculosus* collected in Durango, México, off Highway 40 near the Durango/Sinaloa border. A neonate (ca. 160 mm TL) collected on 28 June had a noticeable mid-body bulge. Gentle palpation of the abdomen revealed the bulge to be a juvenile lizard based on size and body proportions. Later analysis of the fecal remains confirmed the prey's identity as *Anolis nebulosus*. This species is common in the area, and because of their slender shape and ground-dwelling habits might account for a large portion of juvenile *C. l. maculosus* diet. At 1105 h on 1 July an adult female *C. l. maculosus* (540 mm TL, 74.6 g) was collected under a prickly pear (*Opuntia* spp.) ca. 25 cm away from a large adult male *Sceloporus jarrovii jarrovii* (200 mm TL). By 1128 h the lizard

had died. Examination of the lizard revealed two fang puncture marks on its hind leg. Analysis of fecal remains from a third *C. l. maculosus* (adult male) revealed the dorsal guard hairs of an unidentified small mammal.

We thank Deron Hartman for his assistance in the field.

Submitted by **ROBERT W. BRYSON, JR.**, Department of Biology, Sul Ross State University, Alpine, Texas 79832, USA, **JAVIER BANDA** and **DAVID LAZCANO**, Laboratorio de Herpetología, Universidad Autónoma de Nuevo León, Apartado Postal - 513, San Nicolas de los Garza, Nuevo León, C.P. 66450, México.

CROTALUS PRICEI PRICEI (Twin-Spotted Rattlesnake). **HABITAT SELECTION**. *Crotalus pricei pricei* typically inhabit high elevation temperate pine-oak forest (>1900 m) and are most commonly associated with rocky habitats (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed. Univ. California Press, Berkeley, California. 1533 pp.; Armstrong and Murphy 1979. The Natural History of Mexican Rattlesnakes. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 5:1–88; Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Comstock Publ. Assoc., Ithaca, New York. 425 pp.). Armstrong and Murphy (*op. cit.*) found *C. p. pricei* often utilized rocks for basking and cover. They also stated that this species may be found in grassy mountain valleys where there is an abundance of prey. Here we report on the collection of three *C. p. pricei*, all found using woody cover.

We collected three specimens of *C. p. pricei* in the Sierra del Nido mountains in Chihuahua, México, on 22 July and 24 July 2000. All specimens were collected in a high elevation pine-oak forest at elevations ranging from 2732 to 2748 m. One specimen (adult female 385 TL, 43.5 g) was collected in a grassy meadow at the base of a tree stump, a second (adult male 380 TL, 33.4 g) among the branches of a fallen dead tree, and the third (adult male 425 TL, 41.4 g) in the hollow of a dead stump. Heavy logging had occurred in the past in this area and there were numerous dead pine (*Pinus* spp.) stumps, logs, and fallen branches and trees in the area. All three specimens encountered were using the cover provided by the dead stumps and branches. *Barisia levicollis* and *Sceloporus grammicus* appeared to be most abundant in or near the dead stumps, logs, and branches as well and are both probable prey items of *C. p. pricei*. These observations suggest that *C. p. pricei* might use woody cover when available and suggest that woody cover might be an important habitat component of some populations.

We thank Deron Hartman and Ray Queen for their assistance in the field and James Mueller for reviewing the manuscript and providing additional comments.

CROTALUS VIRIDIS CONCOLOR (Midget Faded Rattlesnake). **MAXIMUM LENGTH.** On 30 June 2000, a male *Crotalus viridis concolor* was found basking on a dirt road within our study site near Green River, Sweetwater County, Wyoming, USA. Measurements were taken prior to radio transmitter implant surgery while the snake was under halothane inhalation anesthesia. The snout–vent length (SVL) was 70.6 cm, total body length (TBL) (excluding rattle) was 75.6 cm, and body mass was 205 g. Klauber (1972. Rattlesnakes. University of California Press, Berkley and Los Angeles, California. 1533 pp.), Baxter and Stone (1992. Amphibians and Reptiles of Wyoming, 2nd ed. Wyoming Game and Fish Department, Cheyenne, Wyoming. 137 pp.) and Hammerson (1982. Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver, Colorado. 131 pp.) all suggest that *C. v. concolor* usually obtain lengths less than 65 cm, whereas Cox and Tanner (1995. Snakes of Utah. Brigham Young University, Provo, Utah. 92 pp.) suggest that they do not reach lengths exceeding 92 cm. This is only the second specimen reported to exceed 65 cm in length. The first account was a specimen that measured 74 cm SVL and 77.5 cm TBL (T. Patton, pers. comm.). The body mass was not measured and the length measurements may have been slightly off because it had been run over by a vehicle and the rattles had been removed.

ERYTHROLAMPRUS AESCULAPII (Coral-patterned Snake). **DIET**. In a study of the stomach contents of *E. aesculapii* deposited in the herpetological collection of the Museo de Historia Natural La Salle, Caracas (MHNLS), we found a specimen (665 mm SVL; MHNLS 11711), collected from the right margin of the Ariza River in Bolívar State, Venezuela, 290 m elevation, having in its gut a snail-eating snake, *Dipsas catesbyi* (465 mm SVL; MHNLS 14971). The *D. catesbyi* was partially digested from the anal plate to the tail. This supports previous reports that *E. aesculapii* swallows other snakes tail first (Marques e Puorto 1994. Rev. Brasil. Biol. 54:253–259). This is the first report of an identified prey item from *E. aesculapii* in Venezuela and the second report of *Dipsas* in the diet of *E. aesculapii* in South America. Marques and Puorto (*op. cit.*) found that the prey of adult *E. aesculapii* consisted of only terrestrial colubrids, with the exception of a single specimen of *Dipsas incerta*. *Dipsas catesbyi* is a colubrid with arboreal habits that may be vulnerable to predation from *E. aesculapii* only when it descends to the ground to feed on snails.

LIOCHLOROPHIS* (= *OPHEODRYS*) *VERNALIS (Smooth Green Snake). **REPRODUCTION.** Reproductive characteristics of *Liochlorophis vernalis* in the Rocky Mountains and southwestern United States are relatively poorly known (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico

Press, Albuquerque. 431 pp.; Hammerson 1999. Amphibians and Reptiles in Colorado, 2nd ed. Univ. Press of Colorado and Colorado Div. Wildlife, Niwot, Colorado. 484 pp.). In this note, I provide information on eggs and neonates from northeastern New Mexico.

On 28 July 2000, I found 13 *L. vernalis* eggs under a ca. 5 cm thick, rock slab near State Highway 518, 5.5 km by road W of La Cueva, Mora Co., New Mexico, USA (2188 m elev.). The nest was on a south facing, 30–40° slope between the highway and the Mora River floodplain, and the smooth-shelled, whitish eggs were loosely clustered in an indistinct depression in the soil beneath the slab. Twelve eggs were collected (a 13th was damaged); 10 of the eggs were adhered to each other in groups of two, two, and six, which prevented individual measuring and weighing of some. Total mass of the 12 eggs was 31 g, with an average mass per egg of 2.6 g. Egg length and width (in mm, N = 9) averaged 26.4 (24–29) and 12.0 (11–15).

Eggs were incubated at 22–32°C on moist paper towels. The adhered group of six eggs hatched 9–11 August, and five other eggs hatched 13–14 August (one failed to hatch). Neonates numbered six males and five females, and dorsal coloration was a dull gray-green rather than the typical bright green of adults. Neonate SVL and total length (in mm) averaged 104.8 (93–114) and 146.9 (134–154), respectively, and neonate mass averaged 1.2 g (1.0–1.3). Female SVL/total length ratios (0.73 ± 0.01 SE) were significantly greater than those of males (0.70 ± 0.01 SE; $t = 2.78$, $P < 0.03$).

Degenhardt et al. (1996, *op. cit.*) noted that *L. vernalis* clutches might number 2–18 eggs, with 6–7 more typical. It is possible that two clutches were present in the cluster of 13 eggs as there was > 1 day separation between hatching dates of the adhered group of six and the remaining eggs. Communal oviposition has been reported in northern and eastern populations (e.g., Gregory 1975. Copeia 1975:185–186; Lawson 1983. Herpetol. Rev. 14:20) and probably also occurs in the southwestern part of the range.

Neonates and egg remains are deposited in the University of New Mexico Museum of Southwestern Biology (MSB 61990-62000). I thank C. W. Painter for comments.

MORELIA BOELENI (Boelen's Python). **ENDOPARASITISM**. On 18 November 2000 a wild collected *Moreila boeleni* was acquired by the Dallas Zoo. Upon arrival this specimen was determined to be a female weighing 7.3 kg with a snout–vent length of 230 cm and a tail length of 29 cm. During routine cage maintenance several specimens of the nematode *Ophidascaris papuanus* were found. A previous report details the treatment of *O. papuanus* in a long-term captive specimen of *M. boeleni* (Hartdegen et al. 1998. ARAV 8,1: 8).

Submitted by **RUSTON W. HARTDEGEN**, Department of Herpetology, Dallas Zoo, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA, and **KATHRYN C. GAMBLE**, Department of Veterinary Medicine, Dallas Zoo, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA.

OHPIOPHAGUS HANNAH (King Cobra). **DIET**. *Ophiophagus hannah* primarily feeds on rat snakes (*Ptyas mucosus*) but also preys on other snakes, lizards (Whitaker 1978. Common Indian Snakes: A Field Guide. Macmillan and Co., New Delhi. 154 pp.), and the porcupine *Hystrix indica* (pers. obs.). Here I discuss two observations of *O. hannah* preying on the Indian rock python (*Python molurus*) on the western slopes of the Western Ghats of Karnataka, India. The area is a matrix of protected forests and cultivated regions. Most of the cultivated regions contain paddy crops, arecanut gardens, and a few rubber and cashew plantations. The forest is characterized by semi-evergreen vegetation and receives >5000 mm of precipitation annually.

The first observation occurred on 12 October 1997 at 1025 h in Kudremukh National Park, Dakshina Kannada, India. People from a nearby village discovered an *O. hannah* (4.88 m total length) entwined with a *P. molurus* (3.66 m total length). The snakes remained entwined for more than 2 h in a paddy field. The people that had gathered disturbed the snakes and the *O. hannah* released the *P. molurus*. The partially paralyzed *P. molurus* crawled into a crevice in the laterite rock near the field and the *O. hannah* fled into a nearby thicket. After the crowd of people left, the *O. hannah* returned at 1545 h and searched for, found, and ate the *P. molurus*.

The second observation occurred on 12 November 1998 at 1330 h in Subramanya, Dakshina Kannada, India. Subramanya is a small township on the edge of the Pushpagiri Wildlife Sanctuary. A forest guard reported that an *O. hannah* (ca. 4.26 m total length) was feeding on a *P. molurus* (ca. 1.8 m total length). The *O. hannah* held the *P. molurus* at the mid-section. After ca. 30 min. the *P. molurus* bit the *O. hannah* but could not escape. With in 1 h, the *P. molurus* was paralyzed. It took the *O. hannah* ca. 15 min. to position the *P. molurus*. The *O. hannah* produced much saliva as it began to swallow the *P. molurus*. Swallowing by the *O. hannah* began slowly but accelerated when over half of the *P. molurus* was ingested. The *O. hannah* raised its hood to ca. 60 cm above the ground before the last 30 cm of the *P. molurus* was swallowed. It took 2 h for the *O. hannah* to completely swallow the *P. molurus*.

PHILLODRYAS BARONI BARONI (Baron's Racer). **ENDOPARASITISM**. On 14 November 2000 three (1.2) adult wild collected *Phillodryas baroni baroni* were acquired by the Dallas Zoo. The one male weighed 190 g with a snout–vent length (SVL) of 91 cm and a tail length (TL) of 31.2 cm. Female mean measurements were as follows: 285 g with an SVL of 101.8 cm and a TL of 32.5 cm. During routine cage maintenance, several specimens of *Hexametra boddaertii* were voided with feces.

Submitted by **RUSTON W. HARTDEGEN**, Department of Herpetology, Dallas Zoo, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA, and **KATHRYN C. GAMBLE**, Department of Veterinary Medicine, Dallas Zoo, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA.

PHILOTHAMNUS CARINATUS (NCN). **REPRODUCTION and GROWTH.** Nothing is known on the reproduction and growth of *P. carinatus*, a species of green bush snake (Colubridae) widespread in the Guinea-Congo forest (Chippaux.1999. Les Serpents d'Afrique Occidentale et Centrale. IRD Editions, Paris. 278 pp.). Here we provide data on specimens captured in southeastern Nigeria. The study area (Odukpani, Cross River State, 04°49'N, 08°21'E), a secondary thick forest surrounded by a mosaic of suburbs, farms, and plantations, is tropical with a pronounced wet season occurring from May to September.

Three gravid females were captured at Odukpani during 1999. The first (SVL = 53.4 cm) laid three large eggs on 3 January, the second (SVL = 51.7 cm) laid four large eggs on 9 December, and the third (SVL = 66.2 cm) laid three large eggs on 18 December. No gravid females were captured during any other period of the year.

Two newly-hatched *P. carinatus* (with fully evident umbilical scars) were captured and scale-clipped at the study area. One (unsexed, SVL = 16.7 cm, tail = 5.9 cm) was captured on 22 April 2000, and another (SVL = 17.1 cm, tail = 6.8 cm) on 15 April 1999. The latter (a male) was recaptured on 2 February 2000 (SVL = 25.2 cm, tail = 9.7 cm) 36 m linear distance from the first site of capture. The growth of this specimen was 8.1 cm SVL and 11.0 cm total length in < 300 days. Therefore, we calculated a growth rate for this individual of 0.027 cm x d^{-1} SVL, or 0.037 cm x d^{-1} total length. A voucher at the Zoological Museum of Copenhagen (ZMUC 601598), captured at Osomba (Cross River State) on 16 February 1959, was nearly identical in size (SVL = 25.0 cm, tail = 9.8 cm) to our marked male at the recapture time. This voucher also probably hatched in April, assuming a similar growth rate as that recorded in our marked specimen.

Our data, although preliminary, demonstrate that in this species eggs are laid during the dry season, and hatch during the interphase between end of dry season and the onset of wet season, exactly as seen in *P. h. heterodermus* from southeastern Nigeria (Akani et al. 2001. Herpetol. Rev. 32:50–51). Whether *P. carinatus* may have multiple periods of egg laying (and thus also of hatching) is not known. Moreover, the fact that our scale-clipped juvenile was recaptured very close to the site of first capture after almost 300 days suggests that young *P. carinatus* may be very sedentary throughout their first year of life (daily movement rate = 0.12 m x d^{-1}).

This study also extends the known range of *P. carinatus* in Nigeria. Before, it was known only from southwestern Nigeria close to the political border with Benin Republic (i.e., Lagos State, cf. map in Chippaux 1999, *op. cit.*), but our records (both field data from Odukpani and two vouchers from Osomba: ZMUC 601597 and ZMUC 601598) came from Cross River State (capital: Calabar) in the extreme southeastern part of the country, near the political border with Cameroon.

We thank E.N.I.-Agip Environmental Department, Aquater S.p.A., T.S.K.J. Nigeria Ltd., Ecosystem s.r.l., F.I.Z.V., and Chelonian Research Foundation (Linnaeus Fund) for financially supporting parts of our long-term research in Nigeria. Claudia Corti is gratefully thanked for measuring vouchers at the Zoological Museum of Copenhagen, Jens Rasmussen (ZMUC) for allowing measurements of specimens, Francesco M. Angelici, Zena Tooze, Edoardo Politano, and Dario Capizzi for providing fieldwork and/or data input.

AKANI**, Department of Biological Sciences, The Rivers State University of Science and Technology, P.M.B. 5080, Nkpolu, Port Harcourt, Rivers State, Nigeria (e-mail: g.c.akani@usa.net), and **LUCA LUISELLI**, Institute of Environmental Studies "Demetra", via dei Cochi 48/B, I-00133 Rome, Italy, and F.I.Z.V., via Olona 7, I-00198 Rome, Italy (e-mail: lucamlu@tin.it).

THAMNOPHIS COUCHII (Sierra Garter Snake). **MAXIMUM SIZE and RECORD LITTER SIZE.** Rossman et al. (1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman. 332 pp.) reported that *Thamnophis couchii* attains a maximum size of 957 mm SVL (based on LSUMZ 55661, an adult female from Tulare Co., California, USA, with an incomplete tail). This same snake also gave birth to 38 neonates, the largest litter recorded for this species (Rossman et al., *op. cit.*).

An adult female *T. couchii* collected by Ted Thompson in May 2001 from Pine Flat Reservoir, Fresno Co., California gave birth to 39 young on 6 August 2001. Following parturition, she measured 1000 mm SVL. Her tail was incomplete. Using the tail length/total length ratios for adult females given by Rossman et al. (*op. cit.*), her estimated total length was 1259–1341 mm. The adult female and all neonates were released at the original collection site.

Submitted by **ROBERT W. HANSEN**, 16333 Deer Path Lane, Clovis, California 93611-9735, USA; e-mail: rwh13@csufresno.edu.

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). **DIET.** The diet of *Thamnophis sirtalis* includes invertebrates, fish, amphibians, mammals, and birds (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman, Oklahoma. 332 pp.; Wright and Wright. 1957. The Handbook of Snakes of the United States and Canada. Comstock, Ithaca, New York. 1105 pp.), as well as carrion. Carrion feeding usually involves the ingesting of a previously killed amphibian (Palmer and Braswell. 1995. Reptiles of North Carolina. University of North Carolina Press, Chapel Hill, North Carolina. 412 pp.; Ruthven. 1908. Bull. U.S. Natl. Mus. 61:1–201). However, literature reports of *T. sirtalis* consuming dead birds are scarce. Ruthven (*op. cit.*) reported an incident where a *T. sirtalis* was observed swallowing a yellow warbler (*Dendroica petechia*) that had been seen dead the previous day. A more recent observation by Sajdak and Sajdak (1999. Herpetol. Rev. 30:229) of a DOR *T. s. sirtalis* killed while in the act of swallowing a DOR passerine bird provides an additional record of this behavior. Here I report a third incident of carrion consumption by *T. s. sirtalis*.

On 28 July 1998, I discovered an adult female *T. s. sirtalis* (ca. 500 mm TL) under a wooden panel, 1.1 km ENE of the Erie International Airport, Erie Co., Pennsylvania, USA. The snake had a considerable swelling near mid-body suggesting a recent meal, but otherwise appeared thin and under weight, similar to that of a postpartum female. Upon handling, the snake disgorged the partially digested feet and tarsi of a bird. The structure of the feet and tarsi were characteristic of the thrush family (Turdidae). Based on the size of the bird limbs and the appearance that the limbs were gnawed, it is apparent that the snake consumed the limbs as car-

rion and not an entire bird.

I thank Arthur Hulse for reviewing this manuscript and offering helpful comments and suggestions.

Submitted by **BRIAN GRAY**, 1217 Clifton Drive, Erie, Pennsylvania 16505, USA.

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). **WINTER PREDATION.** Predation by red-tailed hawks on snakes has been well documented (Knight and Erickson 1976. Raptor Res. 10:108–111; Fitch and Bare 1978. Trans. Kansas Acad. Sci. 81:1–13; see Preston and Beane 1993. *In* Poole and Gill [eds.], The Birds of North America, No. 52, pp. 1–20. Acad. Nat. Sci., Washington, D.C. The American Ornithologists' Union). In particular, red-tailed hawks are known to prey on members of the genus *Thamnophis* (Knight and Erickson, *op. cit*; Fitch and Bare, *op. cit.*; Ernst and Barbour 1989. Snakes of Eastern North America. George Mason Univ. Press, Fairfax, Virginia. 282 pp.). On 31 January 2001, one of us (JK) salvaged a red-tailed hawk (*Buteo jamaicensis* "*kriderii*") along U.S. Hwy 49, ca. 2.4 km S Weiner, Poinsett County, Arkansas, USA (T11N, R2E, Sec 18; 35°35'57"N, 90°54'90"W). Habitats on either side of the highway are mainly temporary, vegetated, aquatic ditches normally filled with overflow water from rice fields. Upon closer examination of the hawk, the tails of two eastern garter snakes (*Thamnophis s. sirtalis*) were found protruding from a neck wound. Complete dissection of the hawk revealed that only the tails along with small portions of the posterior abdominal region of both snakes (an adult male and female) remained in the gullet of the bird. This observation suggests that by exiting overwintering retreats to presumably bask in brief periods of warm weather (as was the case here), *T. s. sirtalis* becomes highly susceptible to avian predators which primarily hunt for small mammals in habitats associated with fallow agricultural fields during the winter. The snakes were deposited in the Arkansas State University herpetological collection (ASUMZ 25498–25499). We thank Jim Bednarz for verifying the "kriderii" morph of the red-tailed hawk.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 33, Number 1 (March 2002). Additional note: The responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extensions unless a thorough literature review has been completed.

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). USA: OHIO: Erie Co: Kelly's Island. On 20 September 2000, a sub-adult *Ambystoma opacum* was found under a board at N 41°37.116'N, 82°42.419'W on Kelley's Island. The animal was approximately 56 mm total length. Identity verified by Ronald A. Nussbaum. Photographic specimen No. 7240 UMMZ. In addition, on 6 August 2001 one of the authors (KMS) found a dead adult at N41°35.604'N, 82°41.387'W. This animal was 105 mm total length and is deposited at the Cleveland Museum of Natural History (8911). Identity verified by Timothy O. Matson. Although Lowcock and Bogert (1992. Can. Field Nat. 106:2) previously recorded this species on Kelley's Island, only larvae were present. We believe that the specimens reported herein are the first of post-metamorphic individuals on the island.

Submitted by **WILLIAM P. FLANAGAN III**, The National Amphibian Conservation Center, Detroit Zoological Institute, 8450 West Ten Mile, Royal Oak, Michigan 48068, USA (e-mail: Bflanagan@detroitzoo.org; Bflanagan@detroitzoo.org), **KRISTIN M. STANFORD**, Northern Illinois University, Department of Biological Sciences, Dekalb, Illinois 60115, USA (e-mail: kristins@niu.edu), **KENT A. BEKKER**, The Toledo Zoo, Department of Herpetology, 2700 Broadway, Toledo, Ohio 43609, USA (e-mail: herpers@toledozoo.org).

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: FLORIDA: Gulf Co.: 0.4 km W of Two Pen Ridge Road, 0.9 km N of Stone Mill Creek (NE 1/4 Sec 31, T3S, R10W). 17 January 2002. John G. Palis. SIUC H–6547. Verified by J. G. Steward. Adult male found under a log within an isolated *Taxodum ascendens* pond. First record for county (Ashton and Ashton. 1988. Handbook of Reptiles and Amphibians of Florida, Part Three: The Amphibians. Windward Publ., Miami, Florida. 191 pp.).

Submitted by **JOHN G. PALIS**, P.O. Box 387, Jonesboro, Illinois 62952, USA.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: TEXAS: Houston Co: Davy Crockett National Forest, compartment number 56, approximately 800 m southeast of the intersection of Forest Service roads 503 and 503B. 30 January 2002. Daniel Saenz. TCWC 84718. Verified by James R. Dixon. New county record (Dixon 2000. Amphibians and Reptiles of Texas, Second edition, Texas A&M Press, College Station, 421 pp.). The adult salamander (56 mm SVL and 94 mm TL, tip of tail missing) was caught in a funnel trap in a manmade wildlife mitigation pond (Davy Crockett National Forest wildlife pond 56–2). This may be the westernmost record for *Ambystoma talpoideum* and the first record for the Neches River drainage.

Submitted by **DANIEL SAENZ**, Wildlife Habitat and Silviculture Laboratory, Southern Research Station, USDA Forest Service, Nacogdoches, Texas 75962, USA, **CORY K. ADAMS** and **JAMES B. JOHNSON**, Department of Biology, Stephen F. Austin State University, Nacogdoches, Texas 75962, USA.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: ARKANSAS: Clark Co: 6.5 km W Arkadelphia, Sec. 10 T7S R20W. 19 February 2002. Martin Campbell. Henderson State University collection 898. Clark Co: 8 km NW Gurdon, SW 1/4 Sec. 27 T9S R21W. 23 February 2002. Renn Tumlison. Henderson State University collection 899, 903–906. Verified by Stan Trauth. Gurdon record includes one adult and several larger specimens of larvae from a permanent woodland pond without fish. First records for Clark Co., helps verify northward range extension in the West Gulf Coastal Plain toward the Ouachita Mountains, and fills gap between records in adjacent Dallas Co. and nearby Garland Co. (Trauth et al. 1993. Proc. Arkansas Acad. Sci. 47:154–156).

Submitted by **RENN TUMLISON** and **MARTIN CAMPBELL**, Departments of Biology and Chemistry, Henderson State University, Arkadelphia, Arkansas 71999, USA.

AMBYSTOMA TIGRINUM (Eastern Tiger Salamander). USA: INDIANA: Perry Co.: Highway 66. 1.4 km S of Highway 70 (Sec 4, T5S, R1W). 15 December 1995. John G. Palis. SIUC H–6548. Verified by J. G. Stewart. Fresh DOR gravid female collected during a light rain at 2008 h. First record for county (Minton 2001. Amphibians and Reptiles of Indiana. Second Ed. Indiana Academy of Science, Indianapolis, Indiana. 404 pp.)

Submitted by **JOHN G. PALIS**, P.O. Box 387, Jonesboro, Illinois 62952, USA.

NECTURUS MACULOSUS MACULOSUS (Common Mudpuppy). USA: WISCONSIN: Ashland Co: Iron River just above confluence with Bad River, at Forest Road 184 (T44N, R3W, Sec 26). 24 May 1999. John Lyons and Philip A. Cochran. Milwaukee Public Museum (MPM) 31830. Verified by Gary Casper. Juvenile collected by electrofishing confirms presence of mudpuppies above a barrier waterfall on a tributary to Lake Superior's south shore, in this case Copper Falls on the Bad River (Cochran 1999. Bull. Maryland Herpetol. Soc. 35:4–13). Cestodes in the intestine of this specimen were probably *Proteocephalus loennbergii*, which has been reported from *N. maculosus* in southeast Wisconsin (Coggins and Sajdak 1982. Proc. Helminthol. Soc. Washington 49:99–102), but identification to species was precluded by the use of ethanol to preserve the mudpuppy. Their presence permits the inference that, in addition to *N. maculosus*, the parasite and the crustacean host for its procercoid larvae were also able to colonize the upper Bad River system prior to the establishment of Copper Falls.

Submitted by **PHILIP A. COCHRAN**, Biology Department, Saint Mary's University, Winona, Minnesota 55987, USA; **JOHN LYONS**, Wisconsin Department of Natural Resources, 1350 Femrite Drive, Monona, Wisconsin 53716, USA; and **MATTHEW G. BOLEK**, School of Biological Sciences, University of Nebraska–Lincoln, Lincoln, Nebraska 68588.

PLETHODON IDAHOENSIS (Coeur d 'Alene Salamander). USA: MONTANA: Ravalli Co: Lake Como Falls (UTM Zone 11, E709158, N5102643, 1305 m elev). 10 October 2001. Bryce A. Maxell. Idaho State Museum of Natural History (IMNH) 1919: 47.5 mm SVL, 93 mm TL; and IMNH 1920: 41 mm SVL, 80 mm TL). Verified by Charles R. Peterson. This record extends the known range ca. 45 km south and 60 km east of the nearest known localities in Montana and Idaho, respectively (Wilson et al. 1997. Great Basin Nat. 57[4]:359–362). Both individuals were found at 1720 h at 5°C under moss-covered cobble in a waterfall spray zone. The locality is within the geographic area predicted to have suitable climatic and geologic attributes and indicates that even more southerly localities in the Bitterroot River drainage are possible (Wilson and Larson 1998. Northwest Sci. 72[2]:111–115).

Submitted by **BRYCE A. MAXELL**, Wildlife Biology Program, University of Montana, Missoula, Montana 59812, USA; e-mail: nathist@selway.umt.edu.

PLETHODON SERRATUS (Southern Red-backed Salamander). USA: ARKANSAS: Hot Spring Co: 3.5 km S Oak Bower at DeGray Lake Resort State Park, Towering Pines Trail. 1 February 2002. C. T. McAllister. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26396–26402). Verified by Stanley E. Trauth. New county record (Trauth et al., in prep., The Amphibians and Reptiles of Arkansas). Specimens collected from shortleaf pine-oak habitat off north-central shore of DeGray Lake, a 1972 Corps of Engineer impoundment of the Caddo River in the Athens Piedmont Plateau subdivision of the Ouachita Mountains natural division.

Submitted by **CHRIS T. McALLISTER**, Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA; e-mail: chris.mcallister@tamut.edu.

ANURA

DERMATONOTUS MUELLERI (Mueller's Narrow-mouthed Frog) BRAZIL: GOIÁS: Municipality of Goiânia, Santa Rita Ranch (16°40'47"S, 49°20'04"W). 26 June 1999. D. Alves Lôbo. Centro de Estudos e Pesquisas Biológicas, Goiânia, Goiás: CEPB 373, adult female (SVL 77.1 mm); Municipality of Minaçu, Cana Brava (13°34'12"S, 48°06'52"W). 22 April 2000. I. França e Souza. CEPB/IFS 439–00, adult female (SVL 62.7 mm), and an adult male, CEPB/IFS 568–00 (SVL 55.8 mm). Verified by M. Trefaut Rodrigues. New state records (Cei 1980. Mon. Zool. Ital. [N.S.] Monogr. 2. 607 pp; Frost 1985. Amphibian Species of the World, Allen Press, Lawrence, Kansas, 732 pp; Norman and Naylor 1994. Amphibians and Reptiles of the Paraguaian Chaco, Vol. 1. 281 pp.).

HYLA CINEREA (Green Treefrog). USA: ARKANSAS: Perry Co.: (N34.98921° W092.76386°); NE1/4, SW1/4, Sec. 13, R17W, T4N; on Arkansas Hwy 300, 2 mi ENE jct of Arkansas Hwy 300 and Hwy 9, Harris Brake Wildlife Management Area. 22 October 2001. K. J. Irwin and L. K. Irwin. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26451). Verified by Stan Trauth. AOR adult. First record for county (Trauth et al., in prep., The Amphibians and Reptiles of Arkansas).

Submitted by **LISA K. IRWIN**, U.S. Fish and Wildlife Service, 1500 Museum Road, Suite 105, Conway, Arkansas 72032, USA (e-mail: Lisa_Irwin@fws.gov), and **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us).

HYLA FEMORALIS (Pine Woods Treefrog). USA: FLORIDA: Franklin Co: Dog Island, (N29.80651°, W084.58833°), ca. 150 m W of northern end of airfield. 31 December 2001. L. K. Irwin and K. J. Irwin. Sternberg Museum of Natural History, Ft. Hays State University, Hays, Kansas (MHP 6930). Verified by Travis Taggart. Adult found under log in slash pine-scrub forest. First record for Dog Island (Blaney 1971. Herpetologica 27:406–430).

Submitted by **LISA K. IRWIN**, U.S. Fish and Wildlife Service, 1500 Museum Road, Suite 105, Conway, Arkansas 72032, USA (e-mail: Lisa_Irwin@fws.gov) and **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us).

HYLA PUNCTATA (Polkadot Treefrog): VENEZUELA: TACHIRA: Municipio Uribante: Campamento Siberia. Doradas River, 28 km S of Pregonero (7°46'N, 72°00'W), 950 m. 27 May 2001. Colección de Vertebrados, Facultad de Ciencias, Universidad de Los Andes, Mérida (CVULA–IV 6301). Verified by C. Barrio. First state record and highest elevation recorded for the species in the Venezuelan Andes. Previously known from four localities in Venezuela, two from the delta region of Amacuro, another from Bolívar (Hoogmoed 1979. Zool. Verh. 172:1–46; Barrio 1998. Acta Biol. Venezuelica 18[2]:1–93), and another from Barinas (Barrio et al. 2000. Herpetol. Rev. 31:50), all of which were within savannah lowlands below 600 m elevation.

Submitted by **ANDRES CHACÓN-ORTIZ, AMELIA DIAZ DE PASCUAL,** Facultad de Ciencias, Universidad de Los Andes, Venezuela (e-mail: aecortiz@yahoo.com, adiaz@ciens.ula.ve) and **FRANCISCO GODOY**, Desarrollo Uribante Caparo, filial de CADAFE, Táchira, Venezuela (e-mail: cuencaparo@telcel.net.ve).

HYLA VERSICOLOR (Gray Treefrog). CANADA: ONTARIO: Kenora District. Hwy 804, 0.3 km NE of Ontario Power Generation's Manitou Falls Generating Station (UTM Zone 15: N5603600m, E467800m). 8 May 1993. Wayne F. Weller and Ron Sheehan. Royal Ontario Museum (ROM 32576 [segment 3], audio cassette tape). Verified by Ross D. MacCulloch. Three or four individuals calling at 2200 h from cattail pond (fog and drizzle, air temperature 17°C). An observation of a live adult male on Hwy 804 was made 1 km E at 2355 h, but specimen was not retained. The documented northern range limit in Kenora District of northwestern Ontario is represented by specimens from (west to east) Malachi (UTM Zone 15: N5535000 m, E355000 m, ROM 9686 – August 1947), Kenora airport (UTM Zone 15: N5515900 m, E401600 m, JPB 24697 [J.P. Bogart, University of Guelph]– July 1995), Contact Bay in Wabigoon Lake (UTM Zone 15: N5505000 m, E515000 m, ROM 10049 – June 1963), and Butler (UTM Zone 15: N5479000 m, E581500 m, NMC 24517 – June 1983). Extends range 130 km NE of Malachi, and 110 km NW of Kenora airport. This record represents the northernmost record in Ontario.

Submitted by **WAYNE F. WELLER**, 250 Chercover Drive, Thunder Bay, Ontario P7G 1A2, Canada.

LEPTOLALAX TUBEROSUS. VIETNAM: QUANG NAM PROVINCE: Tra My District: Ngoc Linh Mountain Range (940 m, 15°11'41"N, 108°02'25"E). Nguyen Quang Truong. Verified by Robert F. Inger. AMNH A–163665. First provincial record for Quang Nam (Inger et al. 1999. Fieldiana Zool. 92:5–7, Fig. 2).

Submitted by **RAOUL BAIN**, Center for Biodiveristy and Conservation, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA, and **NGUYEN QUANG TRUONG**, Department of Zoology, Institute of Ecology and Biological Resources Hoang Quoc Viet St., Cau Giay, Hanoi, Vietnam.

LITHODYTES LINEATUS (Sapito Listado). VENEZUELA: BOLÍVAR: Municipio Gran Sabana: Río Ourowapá, right bank of a tributary of the Río Cucurital (5°54'39"N, 62°44'23"W) and in forest on the right bank of the Río Cucurital, 500 m downstream from its confluence with the Río Purumay, 420 m elev. 1–6 April 2000. J. C. Señaris, C. Lasso, and R. Rivero. Museo de Historia Natural La Salle (MHNLS 14884, 14934). Verified by G. Rivas. In Venezuela, this species has been reported from some localities in the state of Amazonas, and Andean piedmont of the states of Trujillo, Táchira and Zulia (Ginés 1959. Mem. Soc. Cienc. Nat La Salle 19:85–146; Rivero 1961. Bull. Mus. Comp. Zool., 126:1–207; Lynch 1979, *In* W. E. Duellman [ed.], The South American Herpetofauna: Its Origin, Evolution and Dispersal, pp. 189–215. Mus. Nat. Hist. Univ. Kansas Monogr. 7; McDiarmid and Paolillo 1988. *In* Brewer Carias [ed.], Cerro Neblina. Resultados de la

Expedición 1983–1987, pp. 667–670, Fudeci, Caracas; Barrio 1999. Herpetol. Rev. 30:50; Barros and Barrio 2001. Herpetol. Rev. 32:114–115). These new specimens, found among roots and leaf litter of *Phenakospernum* sp. (Musaceae), constitute the first documented record for the state of Bolívar, although a previous unvouchered report exists for La Hoyada, near El Paují, 100 km SSE of El Manteco (Barrio 1998. Act. Biol. Venez. 18[2]:1–93). The new locality is of interest because it fills a distributional gap within Venezuela for a frog also known to occur in Colombia, Guianas, Ecuador, Brazil, Peru, and Bolivia (La Marca 1992. Catálogo Taxonómico, Biogeográfico and Bibliográfico de las Ranas de Venezuela. Cuadernos Geográficos 9, Univ. Los Andes, Mérida, Venezuela).

RANA LUTEIVENTRIS (Columbia Spotted Frog). CANADA: YUKON TERRITORY: Bennett Lake, beaver pond on Partridge River tributary stream (60°01'27"N, 135°11'49"W). 18 July 2001. Bennett Lake, pond on south shore of West Arm (60°03'30"N, 134°58'18"W. 18 July 2001. Bennett Lake, Birch Pond on north shore of West Arm (60°04'47"N, 135°00'37"W). 17 July 2001. Collected by Brian G. Slough. Verified by David M. Green. Redpath Museum, McGill University, Montréal (3379, 3381–82). First specimens for the Yukon Territory, although reported from the first two locations (Mennell 1997. Herpetol. Conserv. 1:107–109).

BRITISH COLUMBIA: Pond near Deep Lake, Lindeman Creek drainage (59°46'00"N, 135°07'04"W). 26 June 2001. Photographs (collections limited in Chilkoot Trail National Historic Site by Parks Canada). Pond near Log Cabin, Tutshi River drainage (59°46'20"N, 134°56'00"W). 17 June 2001. Dan Johnson Lake, Lindeman Creek drainage (59°47'37"N, 135°02'31"W). 26 June 2001. Hoboe Creek wetland, Willison Bay, Atlin Lake (59°15'08"N, 134°06'03"W). 12 July 2001. Pond near Lang Lake (59°12'43"N, 129°44' 31" W). 22 July 2001. Collected by Brian G. Slough. Verified by David M. Green. Redpath Museum, McGill University, Montréal (3788, 3376, 3378, 3377, 3380). Royal British Columbia Museum specimens 1394 and 1395 were reportedly collected at the Tutshi River (59°46'N, 135°55'W) (Ovaska 1999. Status Report on the Columbia Spotted Frog, *Rana luteiventris* in Canada, Committee on the Status of Endangered Wildlife in Canada. 38 pp.), however the Tutshi River is at longitude 134°55'W. The Lang Lake location is 5 km north of the Simmons Lake reported by Ovaska (*ibid.*) (National Museum of Canada specimen 19475) (58°53'N, 129°46'W), however Simmons Lake is at latitude 59°11'N.

Submitted by **BRIAN G. SLOUGH**, Yukon Coordinator, Canadian Amphibian Reptile and Conservation Network, 35 Cronkhite Road, Whitehorse, Yukon Territory, Y1A 5S9, Canada; e-mail: bslough@yknet.yk.ca.

RHACOPHORUS ORLOVI (Orlov's Tree Frog). VIETNAM: QUANG BINH: Phong Nha - Ke Bang (17°01–34'N, 106°15–18'E). 27 August to 1 September 2001. Thomas Ziegler, Hans-Werner Herrmann, and Vu Ngoc Thanh. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany (ZFMK 75798–75803). VIETNAM: NINH BINH: Cuc Phuong. April 1998. Roland Männel. Staatliche Naturhistorische Sammlungen Dresden, Museum für Tierkunde (MTKD 40764). All verified by Wolfgang Böhme. *Rhacophorus orlovi* was recently described from the South of Ha Tinh Province (18°00–06'N, 105°58'–106°06'E) in Vietnam (Ziegler and Köhler 2001. Sauria 23:37–46). The new findings from Phong Nha - Ke Bang near the Laotian border in Quang Binh Province, which borders Ha Tinh Province in the north, represent the first provincial record and the southernmost record of the species (Ziegler and Herrmann 2000. Biogeographica 76:49–62). The specimen from Cuc Phuong represents the first record for Ninh Binh Province, being separated from the type locality in Ha Tinh Province by the northern Provinces of Nghe Anh and Thanh Hoa, thus also being the northernmost record of the species. The *R. orlovi* specimen from Cuc Phuong is a juvenile (SVL 24 mm), the specimens from Phong Nha - Ke Bang are subadults and adults. The latter include the largest known female (ZFMK 75800, SVL 52.5 mm) and male (ZFMK 75802, SVL 39.2 mm) of the species.

Submitted by **THOMAS ZIEGLER**, Staatliche Naturhistorische Sammlungen Dresden, Museum für Tierkunde, A. B. Meyer Bau, Königsbrücker Landstraße 159, D-01109 Dresden, Germany; present address: Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, D-53113 Bonn, Germany (e-mail: dr.th.ziegler@t-online.de), **HANS-WERNER HERRMANN**, Zoologischer Garten Köln, Riehler Straße 173, D-50735 Köln, Germany, and **JÖRN KÖHLER**, Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, D-53113 Bonn, Germany.

GYMNOPHIONA

SIPHONOPS PAULENSIS. BRAZIL: GOIÁS: Municipality of Minaçu. 12 November 1996. M. Cândido da Costa. Centro de Estudos e Pesquisas Biológicas, Goiânia, Goiás: CEPB 4881 (SVL 139.5 mm; body weight 26.0 g). Collected at a cerradão habitat in

a Cerrado Vegetational Domain, on the left bank (W) of Tocantins River (14°00'30"S, 48°24'53"W). Verified by M. Wilkinson. *Siphonops paulensis* Boetger 1892, was reported to be present at eastern, southeastern, and southern portions of the Atlantic Forest, (Lynch 1979. *In* W. E. Duellman [ed.], The South American Herpetofauna: Its Origin, Evolution, and Dispersal, pp. 189–215. Univ. Kansas Mus. Nat. Hist. Monogr. 7; Frost 1985. Amphibian Species of the World, Allen Press, Lawrence, Kansas. 732 pp.; Duellman 1999. *In* W. E. Duellman [ed.], Patterns of Distribution of Amphibians: A Global Perspective, pp. 255–328. Johns Hopkins Univ. Press, Baltimore, Maryland) and southern Brazil (Cei 1980. Mon. Zool. Ital. [N. S.], Monogr. 2, 607 pp). In recent studies this taxon was mentioned as being present beyond the Atlantic Forest domain (Kokubum and Menin 2001. Herpetol. Rev. 32:53) at the Municipality of Brasília - DF, Brazil, but the authors did not offer any additional data about the specimen. This is the first record of *S. paulensis* in the state of Goiás, extending its geographic distribution up to 580 km (E) from previously known range (Kokubum and Menin, *op. cit.*).

Submitted by **IVAN FRANÇA E SOUZA** (e-mail: souzai@terra.com.br), **HÉLDER LÚCIO RODRIGUES SILVA** and **NELSON JORGE DA SILVA JR.**, Laboratório de Herpetologia, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás, Ave. Universitária, 1440, Setor Universitário, 74.210-010, Goiânia, Goiás, Brazil.

TESTUDINES

CLEMMYS MARMORATA (Pacific Pond Turtle) USA: CALIFORNIA: Plumas Co: Greenhorn Creek east of Quincy. A sub-adult was observed on 12 August 2001 basking on a log along Greenhorn Creek (678029 N, 4426072 E, 1021 m) (CAS PC 48.150, photo voucher). Verified by Jens Vindum. This is the first known occurrence of *C. marmorata* in Plumas County (Jennings and Hayes 1994. Amphibian and Reptile Species of Special Concern in California. California Department of Fish and Game. Sacramento, California; Koo and Vindum 1999. Amphibians and Reptiles of the Plumas National Forest: Historical Collections and California Academy of Sciences 1998 and 1999. Unpubl. report on file, Department of Herpetology, California Academy of Sciences. San Francisco, California).

Submitted by **PIERRE FIDENCI**, 735 Balboa Street #4, San Francisco, California 94118, USA; e-mail: pfidenci@garciaandassociates.com.

EMYS ORBICULARIS (European Pond Turtle). TURKEY: ICEL: In the moat of Mamure Kalesi (a castle; 36°04'54.42"N, 32°53'42.84"E), Anamur. Discovered at sunset on 10 June 2000 by the authors. MVZ 233303 (photographic voucher). Verified by Jim Buskirk and Ted Papenfuss. First record for Icel Province, Turkey. The nearest reported locality of *E. orbicularis* is Finike, Antalya Province and Seydisehir, Konya Province (both ~200 km away). The distribution of *E. orbicularis* in Turkey is given by Basoglu and Baran (1977. Ege Univ. Fen Fak. Kit. Ser. 76:1–272) and Fritz (1989. Salamandra 25:143–168). This record, along with Finike and Hatay Province, is only the third locality for *Emys* on the Mediterranean coast of Turkey. This record lies in the middle of a gap in the range of *E. orbicularis*. We saw two individuals, but only photographed one. We also observed several dozen *Mauremys caspica rivulata*. *M. caspica* is reported for Icel province, but not from the Anamur region (reported from Silfke and Mersin, >100 km E; Basoglu and Baran, *op. cit.*). The presence of a single, non-endemic turtle (*Trachemys scripta elegans*) in the moat raises the possibility that the *Emys* were introduced, however a natural presence in the Anamur region is very plausible.

HYDROMEDUSA MAXIMILIANI (NCN). BRAZIL: BAHIA: Municipality of Elisio Medrado, Jequitibá Reserve (12°52'S, 39°28'W, 700 m). 8 August 1999. M. A. Freitas, C. Moura, and E. Moraes. Museu de Zoologia da Universidade Estadual de Santa Cruz, Ilhéus, Bahia (MZUESC 107). Municipality of Jussari, São José farm (15°11'S, 39°24'W, 500 m). 10 May–26 June 2001. Collector unknown (MZUESC 1235). Municipality of Boa Nova, Boa Esperança farm (14°19'S, 40°05'W, 730 m). 1 July–12 September 2001. Collector unknown. (MZUESC 1774). Municipality of Barra do Choça, Recanto da Adriana farm (14°57'S, 40°33'W, 850 m). 1–30 September 2001. J. O. Ruas. (MZUESC 2019). Municipality of Pau Brasil, Pratinha farm (15°23'S, 39°35'W, 530 m). 15 November 2001. Collector unknown. (MZUESC 2107). All specimens verified by Miguel Trefaut Rodrigues. The range of this species was previously considered restricted to the states of Espírito Santo, Rio de Janeiro, and São Paulo, Brazil (Ernst and Barbour 1989. Turtles of the World. Smithsonian Inst. Press, Washington, D.C., and London. xii + 313 pp.). These records extend the known distribution of this species at least 600 km north.

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz–UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil (e-mail: lachesis@uesc.br), and **MARCO ANTÔNIO DE FREITAS**, Rua E quadra D lote 11, Jardim Aeroporto, CEP 42700-000, Lauro de Freitas, Bahia, Brazil (e-mail: philodryas@hotmail.com).

KINOSTERNON HERRERAI (Herrera's Mud Turtle). MÉXICO: MÉXICO: Municipality of Temascaltepec, El Tule, on the bank of Temascaltepec River (19°00'N, 100°05'W), 1520 m elev. 17 May 1999. Vicente Mata-Silva and Martín Paredes-Flores. Laboratorio de Ecología, Unidad de Biología, Tecnología y Prototipos, FES-Iztacala, Universidad Nacional Autónoma de México (VMS 235). Verified by Edmundo Pérez-Ramos. First record for the state of México (Camarillo-R and Smith 1992, *In* Strimple and Strimple [eds.], Contributions in Herpetology, pp. 39–41. Greater Cincinnati Herpetol. Soc., Cincinnati, Ohio. viii + 111 pp.). Closest record for this species is from the Gulf lowlands in the state of Hidalgo (Iverson 1992. A Revised Checklist with Distribution Maps of the Turtles of the World. Privately printed, Richmond, Indiana. viii + 363 pp.).

Submitted by **VICINTE MATA-SILVA, AURELIO RAMIREZ-BAUTISTA** (e-mail: raurelio@servidor.unam.mx), **MARTIN PAREDES-FLORES**, and **MANUEL ESPINO-OCAMPO**, Laboratorio de Ecología, UBIPRO, Facultad de

LACERTILIA

ANOLIS DISTICHUS (Bark Anole). USA: FLORIDA: MONROE COUNTY: Florida Keys: Long Key: Keys Marine Laboratory (KML) in Layton, US1 mile marker 68.5. 20 September 2001. Todd Campbell. Verified by Kenneth Krysko. UF 129704. One male collected (55 mm SVL; 3.6 g); another male and two females seen in mangroves near the KML boat ramp. Long Key record. This introduced species was first recorded from Monroe County in Key West in 1977 (Lazell 1989. Wildlife of the Florida Keys. Island Press, Washington D.C. 254 pp.). Also recorded from US1 mile marker 110 on Cross Key in 1983 (UF 121939), and in Marathon, Vaca Key in 1994 (Watkins-Colwell and Watkins-Colwell 1995. Herpetol, Rev. 26:44).

AMPHISBAENA FULIGINOSA FULIGINOSA. BRAZIL: AMAZONAS: TEFÉ (02°42'04.8" S, 64°37'05.9" W), Boa Vista, Amanã Sustainable Development Reserve, Municipality of Tefé. 01 February 2001. Miguel de La Torre Loranca. Instituto Nacional de Pesquisas da Amazônia - INPA, Coleção de Anfíbios e Répteis (INPA 9531). Verified by Tânia Sanaiotti. Adult captured in pitfall trap in secondary forest. This specimen represents the first record for this subspecies in Amazonas State, in northern Brazil. The record enlarges the know distribution to more than 1400 km from Paramaribo, Suriname (Vanzolini 1951. Bull. Mus. Comp. Zool. 106:1–65).

Submitted by **HIPÓCRATES DE MENEZES CHALKIDIS** (e-mail: chalkidis@bol.com.br), **ANA CRISTINA CORDEIRO-DUARTE** (e-mail: cristina@inpa.gov.br.), and **RICHARD C. VOGT** (e-mail: vogt@inpa.gov.br), Instituto Nacional de Pesquisas da Amazônia - INPA, Coleção de Anfíbios e Répteis, Av. André Araujo, No. 2936, C.P. 478, Manaus, Amazonas, Brazil, CEP: 69.083-000.

HEMIDACTYLUS LEIGHTONI (House Gecko). VENEZUELA: ZULIA: Sinamaica, 11°05'N, 71°57'W. 15–16 July 2000. A. Mijares-Urrutia, J. Manzanilla, and R. Rivero. Museo de Historia Natural La Salle, Caracas (MHNLS 15574) and Museo de la Estación Biológica de Rancho Grande, Maracay (EBRG 3786). Verified by C. Molina. First record for Venezuela and easternmost locality for this species (Powell and Maxey 1990. Cat. Amer. Amph. Rept. 493:1–3, as *Hemidactylus brookii leightoni*). Boulenger (1911. Ann. Mag. Nat. Hist. London, sér. 8, 7[3]:19) described *H. leightoni* from Colombia. Kluge (1969. Misc. Publ. Mus. Zool. Univ. Michigan 138:1–78) treated this taxon as a subspecies of *H. brookii*, restricted it to a region extending from the northwestern coast to the central highlands of Colombia, and mentioned that it could be present in western Venezuela. Powell and Maxey (*op. cit.*) listed six subspecies for *H. brookii*, of which two, *H. b. leightoni* and *H. b. haitianus*, occur in America and the Caribbean. Subsequently, Powell et al. (1996. *In* Powell and Henderson [eds.], Contributions to West Indian Herpetology: A Tribute to Albert Schwartz, pp. 51–93. Contr. Herpetol. 12) elevated *H. haitianus* to a full species (see also Powell 1993. Herpetol. Rev 24: 35–137; Powell and Parmerlee. 1993. Dactylus 2:54–55). Likewise, R. Powell (*in litt.*) suggested that *H. leightoni* is distinct from *H. brookii* and *H. haitianus* and recommended that it be considered a full species; consequently restricting *H. brookii* to the Eastern Hemisphere (Rivas et al. 2002. Herpetofauna 23[134]:5–8).

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Apartado Postal 1930, Caracas 1010-A, Venezuela; e-mail: anolis30@hotmail.com.

HEMIDACTYLUS MABOUIA (Amerafrican House Gecko). BRITISH WEST INDIES: Grand Cayman Island: Bodden Town District, Newlands (exterior walls of a house). 12 November 2001. A. C. Echternacht. Verified by R. Powell and S. B. Hedges. Bobby Witcher Memorial Collection (BWMC), Avila College, 06821–22 (gravid adult females). First observed at the site on 24 August 2001 (a minimum of 10 individuals representing both sexes, neonates to adults). This is the first record of the genus and species in the Cayman Islands (Powell et al. 1998. Cat. Amer. Amphib. Rept. 674:1–11).

Submitted by **A. C. ECHTERNACHT**, Department of Ecology & Evolutionary Biology, University of Tennessee, Knoxville, Tennessee 37996-1610, USA (e-mail: echterna@utk.edu), and **F. J. BURTON**, P.O. Box 10308 APO, Grand Cayman, Cayman Islands, British West Indies.

LEIOCEPHALUS CARINATUS ARMOURI (Little Bahama Curly-tailed Lizard). USA: FLORIDA:BREVARD CO: Cocoa Beach, at NE corner of Orlando Ave (Hwy A1A southbound) and S 7th Street. 15 January 2002. K. L. Krysko, F. Wayne King, and Terry Taylor. Verified by Max A. Nickerson. Florida Museum of Natural History, University of Florida (UF 129550). New county record and extends the species range north ca. 158 km of the previous most northern locality along the eastern coast of Florida (Hauge and Butterfield 2000. Herpetol. Rev. 31:53). Additionally, there are four unreported specimens that were collected from the same vicinity: MCZ R–176773–74 collected on 11 January 1991 and AMNH R–3 collected on 1 October 1991. Our specimen provides evidence that this species has been established on Cocoa Beach for more than a decade.

Submitted by **KENNETH L. KRYSKO** (e-mail: kenneyk@flmnh.ufl.edu) and **F. WAYNE KING** (e-mail: kaiman@flmnh.ufl.edu), Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA.

SCINCELLA LATERALIS (Little Brown Skink). USA: FLORIDA: FRANKLIN CO: Dog Island, (N29.80573°, W084.58541°), Dog Island airfield. 31 December 2001. L. K. Irwin and K. J. Irwin. Sternberg Museum of Natural History, Ft. Hays State University, Hays, Kansas (MHP 6942). Verified by Travis Taggart. Adult found under debris along margin of sod runway. First record for Dog Island (Blaney 1971. Herpetologica 27:406–430).

Submitted by **LISA K. IRWIN**, U.S. Fish and Wildlife Service, 1500 Museum Road, Suite 105, Conway, Arkansas 72032, USA (e-mail: Lisa_Irwin@fws.gov) and **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA (e-mail: kirwin@agfc.state.ar.us).

SPHENOMORPHUS TERSUS. MALAYSIA: PENINSULAR MALAYSIA: Selangor; Kepong, Forest Research Institute Malaysia, Sungei Kroh waterfalls; among boulders adjacent to main stream (3°14'N, 101°38'E), ca. 100 m elev. 27 February 2001. Tzi Ming Leong. Raffles Museum of Biodiversity Research: Zoological Reference Collection (ZRC.2.4915, adult female, SVL 70.5 mm, total length 197.7 mm). Verified by Kelvin K. P. Lim. New country record and southerly range extension. Previously known from south Thailand (Khao Wang Hip in Nakhon Sri Thamarat, and Pak Chan estuary at Tasan - Isthmus of Kra) (Smith 1930. Bull. Raffles Mus. 3:1–149). This represents the twelfth species of the genus *Sphenomorphus* known to occur in Peninsular Malaysia (Denzer and Manthey 1991. Raffles Bull. Zool. 39[2]:309–322).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-mail: scip0132@nus.edu.sg), **NORSHAM SUHAINA YAAKOB**, Forest Research Institute Malaysia, Kepong, 52109 Kuala Lumpur, Malaysia, and **INDRANEIL DAS**, Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300 Kota Samarahan, Sarawak, Malaysia.

TROPIDURUS TORQUATUS (Calango). BRAZIL: RIO GRANDE DO SUL: Municipality of Machadinho. 17 September 2001. A. Tomas França. Left bank (S) of Uruguai River (27°34'04"S, 51°35'15"W). Centro de Estudos e Pesquisas Biológicas, Goiânia - GO (CEPB/NAT 977; SVL 240.6 mm). Verified by M. Trefaut Rodrigues. *Tropidurus torquatus* (Wied, 1820) is a widespread species in central, southeastern (Hoogmoed 1979. *In* Duellman [ed.], The South American Herpetofauna: Its Origin, Evolution, and Dispersal, pp. 241–279; Giaretta 1996. Herpetol. Rev. 27:80–81) and southern Brazil (Rodrigues 1987. Arq. Zool. S. Paulo 31[3]:105–203). A single record (two specimens) was obtained from the extreme southern portion of the State of Rio Grande do Sul (Lema and Fabián-Buermann 1977. Iheringia, Sér. Zool. Porto Alegre [50]:61–92). Our specimen confirms the presence of *T. torquatus* in southern Brazil, and extends its range 500 km northward.

We thank the staff of NATURAE - Projetos e Consultoria Ambiental Ltda. at the Cotiara Faunal Rescue Operation for help during fieldwork.

LYSTROPHIS NATTERERI (NCN): BRAZIL: BAHIA: Municipality of Rio de Contas, Vaccaro farm (13°32'S, 41°52'W, 1200 m). 1 April 2000–25 May 2001. Collector unknown. Museu de Zoologia da Universidade Estadual de Santa Cruz, Ilhéus, Bahia (MZUESC 1172). Vicinity of the city of Rio de Contas (13°34'S, 41°48'W, 1050 m) 15–20 May 2001. Collector unknown. MZUESC 1188. Specimens were captured by different collectors and the precise dates of capture are unknown. Dates indicate periods between visits to the farms. Both verified by Miguel Trefaut Rodrigues. Species is known from states of Piauí, Goiás, Mato Grosso do Sul, São Paulo, and Paraná, Brazil, between 45° and 55° W (Hoge et al. 1975. Mem. Inst. Butantan 39:37–50). These records extend the range of *L. nattereri* nearly 280 km in relation to 45°W and represent the new easternmost limit of this taxon.

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz - UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil; e-mail: lachesis@uesc.br.

NERODIA FASCIATA CONFLUENS (Broad-banded Watersnake). USA: ARKANSAS: Perry Co.: NE1/4, Sec 7, T4N, R16W; 2.4 road miles NNE of intersection of Arkansas Hwy 300 and Hwy 216 on Hwy 216. 24 May 2001. K. J. Irwin. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26439). Verified by Stan Trauth. DOR adult male. First record for county and fills hiatus between Saline County to the south and the most northwesterly record in the state in Conway County (Trauth, Robison, and Plummer, ms. in prep.).

Submitted by **KELLY J. IRWIN**, Arkansas Game & Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA; e-mail: kirwin@agfc.state.ar.us.

NERODIA FASCIATA FASCIATA (Banded Watersnake). USA: CALIFORNIA: Sacramento Co: 100 m SE of intersection of Riley Street and Blue Ravine Road (38°39'35"N, 121°09'30"W). June 2000. Peter S. Balfour and Eric W. Stitt. California Academy of Sciences (CAS 215207–215214). Verified by Robin Lawson (CAS) and Rhonda Lucas (CAS). This introduced population was originally discovered by the senior author (PSB) in 1992. The accessioned specimens were collected from a constructed pond and adjacent watershed. Twenty-seven additional captured individuals (many provided by the California Department of Fish and Game) have ranged in length between 63.5 and 130 cm. Seventeen females were dissected and found to contain between 12 and 55 developing ova (mean = 24). Several additional individuals, of all size classes, have been observed prior to and since this collection. This subspecies is native to southern Alabama, northeast through North Carolina (Conant and Collins 1991. Reptiles and Amphibians of Eastern/Central North America. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.).

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blindsnake). USA: VIRGINIA: Newport News, apartment complex at 21st Street and Jefferson Avenue. Eight individuals were seen in the kitchens and back porches of two adjoining apartments; five specimens (USNM 546147–546151) were collected from one apartment.

USNM 546147 (5.5 cm TL) collected alive in kitchen by William Lopez on 27 Sept. 2000. USNM 546148 (6.4 cm TL) collected under a rubber doormat on the back porch on 29 Sept. 2000 by Barbara A. Savitzky and Robert T. Belcher. USNM 546149 (7.5 cm. TL) and 546150 (6.9 cm TL) collected under wood and cardboard debris on the porch together with a dead, desiccated specimen (USNM 546151) on the porch pavement, all by Irene Brumley on 9 November 2000. Verified by Van Wallach (Museum of Comparative Zoology, Harvard University). Wallach noted that all specimens are subadults and difficult to sex; snout scalation is slightly aberrant, but head and body scalation are consistent with *R. braminus*. First record for the state of Virginia and mid-Atlantic coast; third record for mainland USA outside of Florida. First Florida record was in coastal Dade Co. in 1983 (Wilson and Porras 1983. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89), although several Florida populations are now known (Ernst and Brown 2000. Herpetol. Rev. 31:256). Outside of Florida, the other two mainland US localities, New Orleans, Louisiana (Thomas 1994. Herpetol. Rev. 25:34 and Boston, Massachusetts (Wallach et al. 1991. Herpetol. Rev. 22:68 and Jones et al. 1995. Herpetol. Rev. 26:210–211) are coastal ports, as is Newport News. The site is <0.25 km from an international shipping terminal.

New Amphibian and Reptile County Records from Logan County, Illinois, USA

MARIO D. GIAZZON
Department of Biological Sciences, Illinois State University
Campus Box 4120, Normal, Illinois 61790-4120, USA
e-mail: mdgiazz@ilstu.edu

Our early understanding of the geographic distribution of Illinois herpetofauna was largely due to the exhaustive work of Smith (1961). In the last decade, increased field work and examination of museum collections have led to the modification of Smith's work. Several contributions have filled distributional gaps of Illinois amphibians and reptiles at both regional (Markezich and Beckett 2001; Tucker 1994; Wilson 1999) and statewide (Petzing et al. 1998, 2000; Redmer and Ballard 1995) levels. Historically, some counties in Illinois seem to have harbored little herpetological interest and therefore have received very limited organized field work. As a consequence, many species in these counties have not been documented. Logan County is an example of such a county, most likely because 93% of its land is comprised of privately owned cropland and grassland (Illinois Department of Natural Resources 1996). I conducted a survey of the amphibians and reptiles in Logan County from March to August 2001, which resulted in four updated county records and eight new county records.

Previous collection efforts in Logan County have documented six species of amphibians and eight species of reptiles (Phillips et al. 1999). Most of these records are vouchered by only a few specimens, many of which are over 30 years old. One of the goals of this survey was to determine if these species were still present (updated county records) and if some were yet unrecorded (new county records). Updated county records are worth noting because not only do they determine if a species is still present in an area, but they also allow for investigation of possible range extensions within a county. For the purposes of this paper, an updated county record will be defined as a species that has not been documented in Logan County for at least a period of twenty years, a standard adopted by Phillips et al. (1999). Updated county records were determined by accessing museum collection records from the Field Museum of Natural History (FMNH), Chicago, Illinois; the Illinois Natural History Survey (INHS), Champaign, Illinois; the University of Illinois Museum of Natural History (UIMNH), Champaign, Illinois; and the University of Michigan Museum of Zoology (UMMZ), Ann Arbor, Michigan. The specimen catalog number and the year of the most recent voucher specimen have been included for updated county records. New county records were verified by checking the Illinois Herpetological Vouchered Database, which contains data from thirty U.S. collections. A web page developed from this database can be accessed at <http://www.inhs.uiuc.edu/cbd/collections/AmphReptColln/herps.html>. Voucher specimens of new county records were verified by Christopher A. Phillips and deposited at the Illinois Natural History Survey (INHS) in Champaign, Illinois.

Ambystoma texanum. E of Middletown near Polecat Hill; 1.4 km W of int. Co. Rd. 350E and Co. Rd. 1300N (NW 1/4 NE 1/4 Sec. 16, T19N, R4W). 25 March 2001. M. D. Giazzon. INHS 17072.

New county record. Former stream bed of Salt Creek containing temporary pools, bordered to the east by deciduous forest. Four specimens were observed under a large rotten log approximately 8 m from the water's edge.

Pseudacris triseriata. E of Middletown near Polecat Hill; 1.4 km W of int. Co. Rd. 350E and Co. Rd. 1300N (NW 1/4 NE 1/4 Sec. 16, T19N, R4W). 25 March 2001. M. D. Giazzon. INHS 17075. New county record. Former stream bed of Salt Creek containing temporary pools, bordered to the east by deciduous forest. The specimen was found under a flat piece of rotten wood approximately 1 m from the water's edge.

Pseudacris crucifer. E of Middletown near Polecat Hill; 1.4 km W of int. Co. Rd. 350E and Co. Rd. 1300N (NW 1/4 NE 1/4 Sec. 16, T19N, R4W). 25 March 2001. M. D. Giazzon. INHS 17074. New county record. Former stream bed of Salt Creek containing temporary pools, bordered to the east by deciduous forest. The specimen was found under a rotten log approximately 1 m from the water's edge. Only a few males were heard calling at this site upon subsequent visits.

Hyla chrysoscelis/ *Hyla versicolor*. SE of Union; 0.7 km W of int. Co. Rd. 1450E and Co. Rd. 2400N (NW 1/4 NW 1/4 Sec. 21, T21N, R2W). 22 April 2001. M. D. Giazzon. INHS 17152. New county record. Small woodland pond west of Sugar Creek.

Rana catesbeiana. 1.2 km SE of Union; (SE 1/4 NW 1/4 SW 1/4 Sec. 8, T21N, R2W). 25 March 2001. M. D. Giazzon. INHS 17076. Updated county record. Juvenile found dead in pond, possibly killed from recent freeze. Last known voucher specimen was collected in 1953 (INHS 7174).

Nerodia sipedon. NW of Mount Joy; 0.16 km N of int. Co. Rd. 1600E and Co. Rd. 2575N (NE 1/4 NE 1/4 Sec. 10, T21N, R2W). 22 April 2001. M. D. Giazzon. INHS 17151. Updated county record. Found near a small stream that flows under the road. Last known voucher specimen was collected in 1967 (FMNH 208229).

Storeria dekayi. NNW of Lawndale; 0.5 km S of int. Co. Rd. 1600E and Co. Rd. 2250N (SE 1/4 SE 1/4 Sec. 27, T21N, R2W). 22 April 2001. M. D. Giazzon. INHS 17153. New county record. Specimen was DOR.

Thamnophis sirtalis. SW of Chestnut; 0.32 km W of int. Co. Rd. 2000E and Co. Rd. 850N (NE 1/4 SE 1/4 Sec. 5, T18N, R1W). 13 October 2000. M. D. Giazzon. INHS 17353. Updated county record. Last known voucher specimen was collected in 1957 (INHS 8748). Specimen was DOR.

Thamnophis radix. NNW of Rocky Ford Bridge; 0.48 km N of int. Co. Rd. 675E and Co. Rd. 1400N (NE 1/4 SE 1/4 Sec. 6, T19N, R3W). 17 June 2001. M. D. Giazzon and T. C. Giazzon. INHS 17352. Updated county record. Last known voucher specimen collected in 1976 (UMMZ 142860). Specimen was DOR.

Chelydra serpentina. SE of Union; 0.7 km W of int. Co. Rd. 1450E and Co. Rd. 2400N (NW 1/4 NW 1/4 Sec. 21, T21N, R2W). 22 April 2001. M. D. Giazzon. INHS Herpetological Slide 2001.01. New county record. Small woodland pond west of Sugar Creek. The turtle was trapped and subsequently released. A photographic voucher was taken since the specimen was a sexually mature adult.

Chrysemys picta. NNW of Mount Joy; 0.7 km W of int. Co. Rd. 1700E and Co. Rd. 2600N (SW 1/4 SE 1/4 Sec. 2, T21N, R2W). 22 April 2001. M. D. Giazzon. INHS 17150. New county record. Pond next to agricultural fields with a small forested buffer zone.

Trachemys scripta. S of Rocky Ford Bridge; 0.4 km SE of int. Co. Rd. 675E and Co. Rd. 1400N (NE 1/4 NE 1/4 Sec. 7, T19N, R3W). 24 June 2001. M. D. Giazzon and T. C. Giazzon. INHS 17351. New county record. Trapped in first large pond south of bridge and east of Salt Creek.

Acknowledgments.—I thank the landowners of Logan County, who so kindly allowed me to survey their property, Tricia Giazzon for occasional field assistance, and John E. Petzing and Christopher A. Phillips for critically reviewing the manuscript. This project was funded by the Illinois Department of Natural Resources, Natural Heritage Division from contributions to the Illinois Wildlife Preservation Fund (Grant 01-048W). All specimens were collected under Illinois Department of Natural Resources permit number A01.0455.

Nerodia erythrogaster neglecta in Iowa with Comments on Ontogenesis of Color and Pattern

JAMES L. CHRISTIANSEN
Department of Biology, Drake University
Des Moines, Iowa 50311, USA
e-mail: james.christiansen@drake.edu

and

JEFFREY B. LECLERE
878 Galtier Street, St. Paul, Minnesota 55117, USA

Nerodia erythrogaster was known in Iowa from a single specimen collected from the "vicinity of Mount Pleasant" in the 1920s (exact date Chicago Acad. Sci. 7427 uncertain). The lack of heavy ventral pigment or color notes referring to a red belly support

the identification of this specimen as a Yellow-bellied Water Snake, *N. e. flavigaster*. The closest population in Illinois was clearly *N. e. flavigaster* (Blanford and Brandon 1996; Conant and Collins 1998). In 1973 and 1976, two adult specimens with bright red-orange bellies were taken in Muscatine and Louisa Counties and were ascribed to *N. e. flavigaster* by Christiansen and Bailey (1991) on the basis of geographic proximity to that subspecies. Recent collection of additional juvenile and adult specimens allow more thorough analysis, suggesting that the Muscatine-Louisa counties population is probably a relict population of *N. e. neglecta*, the Copper-bellied Water Snake. In this note, we report changes in color and pattern during the first feeding year of life that support the identification of these snakes as a relict population of the *N. e. neglecta*.

FIG. 1. *Nerodia erythrogaster neglecta* color and pattern change from neonate to adult. A and B, adult; C and D, neonate captured in June 2000; E and F, the same juvenile prior to release one year later. All specimens were captured from the Iowa side of the Mississippi River between Muscatine and the union of the Mississippi and Iowa Rivers. The dense ventral black pigment, occasional union of dorsal bands, and red-orange belly are characteristic of this subspecies and provide the first evidence of *N. e. neglecta* in Iowa.

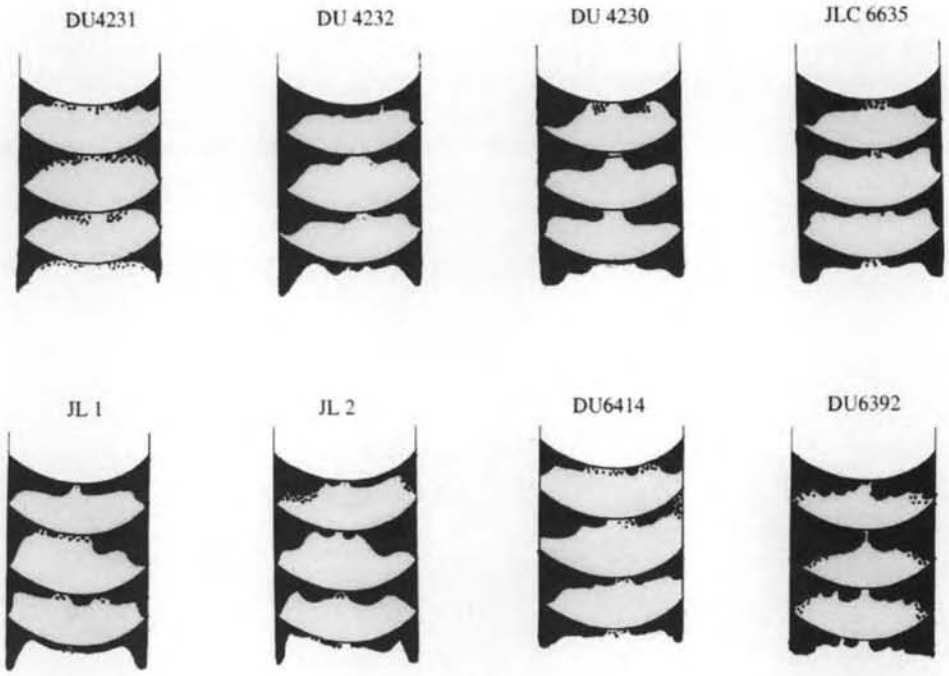

FIG. 2. Drawings of ventral pigment of *Nerodia erythrogaster neglecta* from Iowa. DU 4231 and 4232 were collected south of Muscatine, Iowa in 1973 and 1976 respectively, and are less pigmented than later specimens. All other specimens were taken in eastern Iowa from 1996 through 2000. The two specimens lacking DU numbers were captured as neonates, raised one year, and released in the area where they had been captured. The ventral scutes drawn were in the posterior 1/2 of the body, usually beginning with scute 75.

One adult and five juveniles were acquired from the Muscatine and Louisa counties populations during 1996–2000. Two of the specimens were found DOR and four were taken alive. We describe the pattern and color changes from three neonates captured in May and June 2000 and maintained in captivity seven to eight months on a diet of fish, frogs, and pink mice. The juvenile snakes were photographed when collected in May and June and again February of the following year. Surviving captives were released within the Odessa Wildlife Area near where they were taken.

The ventral coloration of all three adult snakes taken from the Louisa and Muscatine counties populations was bright red-orange and the dorsum was uniform dark brown with only the faintest hint of the underlying juvenile pattern (Fig. 1 A and B). Ventral black pigment was extensive in two of the three adults. The smaller amount of black ventral pigment on the first adult taken contributed to our initial hesitancy in calling this specimen *N. e. neglecta*.

Additional support for the *N. e. neglecta* designation was provided by a DOR juvenile, a DOR neonate, and three neonates taken alive. Both of the DOR specimens had undergone substantial decay and the ventrals were yellow with only traces of orange. All had substantial black ventral pigment (Fig. 2). Many of the anterior dorsal bands of the three living specimens were connected and the ventrals were yellowish anteriorly, light orange at mid body, and red on the tail (Fig. 1C, 1D). Eight months later, the light dorsal bands had darkened considerably and the entire ventral surface had become distinctly red-orange (Fig. 1E, 1F). Fig. 1 (C–F) shows the same snake and is typical of all of the juvenile snakes we maintained in captivity.

The original description of the four subspecies of *N. erythrogaster* by Conant (1949) distinguished *N. e. neglecta* by its bright red-orange ventral color and heavy ventral black pigmentation. Blanford and Brandon (1996) concluded that *N. e. flavigaster* sometimes has orange ventrals but lack the dark black ventral pigment. They also noted that juveniles of *N. e neglecta* tend to have fused dorsal blotches while those of *N. e. flavigaster* lack such fusions. All of our juvenile specimens had at least some fusion of dorsal blotches (Fig. 1C, 1E). Conant and Collins (1998) distinguish *N. e. neglecta* by its red-orange belly, ventral black pigmentation, and irregular, sometimes connecting dorsal blotches of juveniles.

We conclude that the isolated northern population of *Nerodia erythrogaster* in Iowa should be regarded as *N. e. neglecta.* While the ancestral population may have intergraded with *N. e. flavigaster,* the survivors all appear to be exclusively *N. e. neglecta* in appearance. This suggests that *N. e. neglecta* spread westward across northern Illinois while *N. e. flavigaster* was differentiating farther south. The Iowa population of *N e. flavigaster* near Mount Pleasant may be extirpated but the remaining populations of *N. e. neglecta* are afforded endangered species protection in Iowa.

Acknowledgments.—We thank the U.S. Fish and Wildlife Service for funding the search for *Nerodia erythrogaster* in Iowa.

Ten years ago, persons seeking an introductory textbook on herpetology could choose from the early editions of Goin and Goin (1962, 1971), Porter (1972) and Goin et al. (1978). Each of those books had strengths, but many of us teaching herpetology opted to forego a textbook in favor of handouts and reading assignments from the primary literature. In 1993 *Herpetology An Introductory Biology of Amphibians and Reptiles* by George R. Zug appeared in its first edition and became the text of choice for many people teaching introductory courses in herpetology. The appearance in 1998 of *Herpetology*, edited by Harvey Pough, marked a turning point in the development of textbooks in herpetology. Coauthored by six herpetologists—all specialists in their fields—the book presented an authoritative treatment of unprecedented scope and depth. Although in its 1st edition Pough et al. (1998) did have some deficiencies (Bauer 1998), it nonetheless set a new standard for herpetology textbooks. The 2nd edition (Pough et al., 2001) improved on what was already the textbook of choice for many (Zamudio and Chan 2001). Now comes the second edition of *Herpetology An Introductory Biology of Amphibians and Reptiles*, a fully revised and expanded version of the original, the latest entry in the field of textbooks in herpetology.

Textbook publishers are often accused of producing revised editions that differ only in minor detail from preceding editions, simply to defeat the used textbook market. In this case that criticism cannot be leveled at Academic Press, for this second edition bears so little resemblance to its predecessor that to call it a revised edition is something of a misnomer. To assist with this dramatic make-over, Academic Press enlisted the services of Laurie J. Vitt, an evolutionary ecologist who works principally with reptiles, and Janalee P. Caldwell, an expert on amphibian biology. The addition of Vitt and Caldwell provides additional herpetological expertise and a somewhat different perspective; their inclusion nicely complements Zug's broad herpetological expertise. The influence of the new authors is easily seen by examining the number of papers cited on which they are first authors: Vitt 33, up from 5 in the 1st edition; Caldwell 16, up from 2 in the 1st edition. In the bibliography Vitt is cited as first author more than any other person. Thus, the new authors appear to have taken seriously the admonition to "write what you know," for they draw heavily upon their own extensive research experience. In terms of illustrative material, the impact of the new authors is also immediately apparent: of 141 black and white photos, 64 (45.4%) are credited to Vitt and/or Caldwell; of 184 color photos, 57 (31%) are credited to one or both of them.

In a brief preface, the authors set forth their goals in producing this revised edition: "... to update the text to include new concepts and interpretations ... and to provide the evolutionary and classificatory perspective of living amphibians and reptiles circa mid-1999." A second goal is to "... improve the didactic scope of the text ...." The authors serve notice that their classifications are evolution-based, mostly. Thus, they tend to eschew the named categories and fixed levels of the Linnaean hierarchy, except where they find it convenient to use them "... within a textual discussion." Classifications are presented as indented lists of names with those of uncertain monophyly enclosed in quotation marks and with alternative names in parentheses. The biosystematic approach is cladistic, and the authors generally insist on the monophyly of taxa (Anthracosauria is excluded from Amphibia, for example), but as a practical matter they implicitly accept a paraphyletic Reptilia, excluding from treatment the approximately 9000 extant species of feathered dinosaurs.

Comparison of the two editions is presented in Table 1. The second edition is larger in size, has more pages, and thus weighs more. There are more than twice the number of bibliographic entries in the second edition, and nearly twice the number of black and white photos. The second edition includes a glossary, a welcome addition (but see below). Production values of the second edition far exceed those of the original. Larger page size and double column format allows greater flexibility in layout, which is generally efficient and attractive. Especially notable is the inclusion of many color photographs illustrating the diversity of amphibians and reptiles. These are placed conveniently throughout the taxonomic section, rather than being bound in one or a few adjacent signatures.

Many of the errors in the first edition have been corrected. For example, *Hydromantes* replaces *Hydromantoides* (Fig. 1.1 of original), the misstatement that in amphibians rods are the color receptors in the retina (p. 28) has been corrected, Eublepharide (Fig. 17.2) is corrected to Eublepharidae, Trogonophidae (p. 438) is corrected to Rhineuridae, and the misspelling of Mascrene (p. 451) has been eliminated by reference to Mauritius.

The main portion of the book consists of six parts: Evolutionary History, Reproduction and Life Histories, Physiological Ecology, Behavioral Ecology, Population and Community Ecology, and Classification and Diversity, each with two to six chapters. Each chapter begins with an abbreviated table of contents that makes it easy to find particular topics of interest and, with the exception of the chapters in Part VI (Classification and Diversity), each concludes with a short section on additional reading and with a list of references bearing on the main topics covered in the chapter. Ex-

cept for the taxonomic sections, the treatment integrates information on amphibians and reptiles on a conceptual basis, rather than treating the two groups separately, consistent with the current emphasis in organismal biology on multidisciplinary, concept-oriented approaches that integrate rather than divide fields (Pianka et al. 1998).

Part I provides an overview of the evolutionary history of amphibians and reptiles, placing them in the larger context of vertebrate relationships, with emphasis on tetrapod origins and the diversification of amniotes. Chapter 1 is essentially a primer on the theory and practice of systematics. Methods of analysis, kinds of characters, and the rules of nomenclature are briefly treated. Chapter 2 treats the anatomy of amphibians and reptiles, including consideration of embryogenesis, morphogenesis, and heterochrony. I cannot agree with the caption of Figure 2.7, that "When growth is determinant or asymptotic, a sigmoid pattern during juvenile stages is followed by slower growth after sexual maturity and finally curtailment of growth." Normally the term asymptotic growth applies to species that have indeterminant growth in which, subsequent to maturation, the animal grows at an ever-slower rate, thus approaching asymptotic size. Chapter 3 provides a brief introduction to the evolution and diversification of tetrapods and traces the evolution of amphibian and reptilian clades, with special emphasis on those leading to modern forms.

Part II deals with reproduction and life histories. In chapter 4 gamete formation, courtship and fertilization are reviewed, reproductive modes are described, and sexual reproduction is contrasted with non-sexual reproduction. The chapter ends with a consideration of forms of parental care and their evolution. Chapter 5 is concerned with reproductive ecology and life histories. Included here is consideration of temperature-dependent sex determination, the evolution of viviparity, and the evolution of life histories.

Part III is devoted to physiological ecology and contains two chapters, one dealing with water balance and gas exchange (chapter 6), the other with thermoregulation, performance, and energetics (chapter 7).

Part IV, behavioral ecology, consists of four chapters. Chapter 8 treats spacing, movements, and orientation. Included here is consideration of home ranges, territoriality and its evolution, dispersal, homing and orientation. Chapter 9 provides a review of communication in the major groups of amphibians and reptiles, describes various kinds of mating systems, and treats sexual selection and sexual dimorphism. Chapter 10 deals with foraging ecology and diets, including consideration of foraging modes, sensory modalities involved in prey detection, biomechanics of prey capture and handling, and the evolution of diets. Chapter 11 deals with defense and escape. Predator avoidance, mimicry, chemical defense, caudal autotomy, and defenses against the effects of parasitism are discussed.

In Part V chapter 12 is devoted to population ecology, including consideration of population densities, age distributions, life tables, survivorship curves, population growth models, and metapopulation dynamics. The ecology of communities is treated in chapter 13, together with geographical ecology and historical biogeography. Chapter 14, concerned with conservation, discusses the impact of humans on herpetofaunal assemblages, including consideration of the affects of habitat fragmentation, pesticides, acid rain, estrogen-mimicking compounds, and disease. Oddly, amphibian die-offs are treated separately from the issue of declining amphibian populations. Consideration is given to the issues of preservation and management, as well as to captive breeding programs. The authors conclude that augmentation of natural populations, repatriations, and translocations are of questionable value as management tools. This chapter begins with the quote of a 1970 Neil Young lyric " ... *look at mother nature on the run in the 1970's.*" Given the accelerating pace of environmental degradation over the past thirty years, Young's update of that lyric " ... *we've got mother nature on the run in the twenty-first century*" would seem more timely.

Part VI, by far the most extensive section of the book, is concerned with classification and diversity. Chapters 15 through 21 treat caecilians, salamanders, frogs, turtles, crocodilians, lizards and tuatara, and snakes, respectively. A summary overview is provided for each of these major groups, and cladograms of hypothesized familial relationships are presented. Each family (occasionally subfamily) account places the group in a cladistic framework, indicates its probable sister taxon, and includes a list of included taxa. A brief statement concerning distribution is followed by a paragraph characterizing the group, largely on the basis of morphological features. This is followed by a paragraph summarizing salient aspects of the group's biology. Accounts conclude with a list of pertinent references. Distribution maps are provided for each family, with geographical extent depicted in red or blue. As high-level generalizations of distribution the maps are useful, but there are errors in the plotted distributions and there are inconsistencies between the maps and text. For example, although not so indicated on the maps, caeciliids are known from the Pacific slope of Ecuador (Fig. 15.3), and plethodontids extend far north into the Yucatán Peninsula (Fig. 16.7) as do xantusiids (Fig. 20.15). According to Fig. 20.18) gymnophthalmids do not occur north of Honduras, when in fact *Gymnophthalmus speciosus* is known from Belize on the basis of a specimen collected by Laurie Vitt! Helodermatids are shown as not occurring east of the Isthmus of Tehauntepec; in reality *Heloderma horridum* is known from interior valleys of Chiapas, Mexico, and Guatemala (this distribution is more accurately depicted in Fig. 17.13 of the first edition). Leptotyphlopidae (Fig. 21.4) is indicated as not occurring in the base of the Yucatán Peninsula, yet there is a published record for

TABLE 1. Comparison of three text books in herpetology.

No. B/W Photos	75	141	220
Glossary	No	Yes	No
Citations in Text	No	Yes	Yes

Leptotyphlops goudotii from Petén, Guatemala. Accompanying the accounts are color photographs of representative species. These are generally organized in groups of four and are conveniently placed near the appropriate account. The great majority of the images are of high quality, but a few appear out of focus in my review copy (e.g., *Uperoleia mjobergii*, Fig. 17.22; *Scaphiopus holbrookii*, Fig. 17.5). Contrary to the informal convention in biological illustration, the color photographs are oriented with anterior to the right, with the curious exception of *Tylotriton verrucosus*, Fig. 16.9.

The book includes a brief glossary of herpetological terms, introduced with the disclaimer that it "... does not attempt completeness." The glossary is indeed minimalist. Under "K," for example, where one might expect to find such terms as "keel," or "keratin," the sole entry is "karyotype" and the reader is directed to "see chromosome." The book concludes with an extensive bibliography of 2105 entries, a taxonomic index, an author index, and a subject index. The latter is brief, and excludes many terms and concepts that one might expect to find in a comprehensive subject index. There is, for example, no entry for "tadpole," none for "parthenogenesis," and none for "competition." An expanded glossary and a more detailed subject index would make the material of this information-rich volume more easily accessible, especially to readers new to the study of herpetology.

Any book that covers so broad a topic—the biology of amphibians and reptiles—must necessarily be selective, and every reader is likely to find some favorite detail or subject omitted. I was disappointed, for example, that there is no explicit treatment of the historical development of herpetological knowledge, no photographs of the great 19th century herpetologists (e.g., Boulenger, Wiegmann, Cope), and no consideration of the role played by the great museums and universities of the world in the accumulation of herpetological knowledge. Many courses in herpetology begin by placing the accumulation of herpetological knowledge in an historical context; formal treatment of that topic would have been welcome.

Ultimately this book must be evaluated relative to Pough et al. (2001), the sole competing textbook in herpetology. Table 1 provides some basis for this comparison. The two books are roughly comparable in their dimensions, they have similar numbers of pages and numbers of bibliographic entries. They cover much of the same material, using many of the same examples and illustrations. There are differences in emphasis, however, with Pough et al. providing greater depth of coverage on topics such as the biomechanics of feeding and locomotion, and physiology, whereas Zug et al. is particularly strong in their treatment of population and community ecology and life history evolution. Superior production values are apparent in Zug et al. for there is uniformity of type fonts on graphs and diagrams; in Pough et al. a diversity of type fonts and line weights are evident (compare, for example, Figs. 5-23 and 6-13 in Pough et al.). Zug et al. has a glossary, whereas Pough et al. does not. The two differ most conspicuously in the lavish and effective use of color in Zug et al. Where Pough et al. has but 17 color photos, plus one color graphic bound together in a single signature, Zug et al. has 184 color photos placed conveniently throughout the taxonomic sections. Although cosmetic, these differences in production values are important. For a readership that has grown up playing video games and whose attention span (I was once reminded by a University of Miami undergraduate) may not exceed the length of one MTV video, visuals do matter.

Taken as a whole, Zug et al. (2001) is an impressive volume, at once visually pleasing for its attractive layout and high production values, and at the same time intellectually satisfying in its scope and detail. It is well-suited as a textbook for senior undergraduates and graduate students, and it will be a standard herpetological reference for years to come. With publication of the second edition of *Herpetology An Introductory Biology of Amphibians and Reptiles*, Zug, Vitt, Caldwell, and Academic Press have upped the ante in the competition for the herpetological readership, and they pose a severe challenge to Pough et al. for supremacy in the herpetological textbook field.

PUBLICATIONS RECEIVED

Dangerous Wildlife in the Southeast, by F. Lynne Bachleda. 2001. Menasha Ridge Press, Birmingham, Alabama (www.menasharidge.com). xiii + 321 pp. Softcover. US $22.95. ISBN 0-89732-335-1.

This book presents basic information about potentially dangerous animals and plants of the southeastern United States (Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee). Amphibians and reptiles are treated in 62 pages. Six venomous snakes, three crocodilians, five turtles, four frogs and three salamanders have species accounts. Each account begins with a statement of the danger posed by the species (from allergic reactions to potentially lethal envenomation), followed by short summaries of abundance and range, size, description, similar species, diet, habitat and traits (ecological and behavioral features). All of the amphibians and reptiles discussed are illustrated by one or more color photos and in some instances, case histories of attacks or envenomations are provided. Aside from herps the book treats insects and arachnids,

sharks, rays, cnidarians and other marine invertebrates, mammals and a variety of plants. The book is intended for a general audience and stresses prevention and avoidance of dangerous wildlife encounters, but does provide information about first aid and regional contacts for poison control centers and agencies dealing with "problem animals." It should prove to be a useful general guide for hikers, homeowners and naturalists in the region covered.

In Quest of Great Lakes Ice Age Vertebrates, by J. Alan Holman. 2001. Michigan State University Press, East Lansing, Michigan (www.msupress.msu.edu). ix + 230 pp. Hardcover. US $59.95. ISBN 0-87013-591-0.

J. Alan Holman provides a brief introduction to the study of geology, paleontology, and vertebrate evolution as an introduction to this book on the Pleistocene vertebrates of Michigan, Wisconsin, Illinois, Indiana, Ohio, and Ontario. Amphibians and reptiles occupy 22 pages of text. Most of the species treated are still extant in the Great Lakes region today (two salamanders, seven frogs, nine turtles, one lizard and nine snakes). Only the giant tortoise *Hesperotestudo crassiscutata* has become extinct. Accounts of each taxon include information about the appearance, biology, and distribution of the species today (if applicable) as well as a listing of Pleistocene localities and brief comments about the probable paleoecology of the animal. Black-and-white illustrations of the living animal and/or fossil elements are provided for most species. Fishes, birds, and especially mammals make up the remainder of the species accounts. The book is rounded out by chapters dealing with fossil collection and dating, important fossil sites, community structure, Pleistocene extinctions, and an extensive bibliography. It complements the author's earlier books on Pleistocene amphibians and reptiles and should be of special relevance to those interested in the affect of the Ice Age on the fauna of the Upper Midwest.

Herpetological Collecting and Collections Management

Revised Edition

by

John E. Simmons

Herpetological Collecting and Collections Management is the long-awaited revision of John E. Simmons' 1987 handbook. The revised edition is greatly expanded and includes all the techniques needed for field collecting and specimen management in the 21st century. Approximately 180 pp. September 2002.

"The book is excellent. I will make it required reading for all my graduate students and collection personnel."
Janalee Caldwell, Curator, Oklahoma Museum of Natural History

"A detailed, comprehensive treatment"

–Julian C. Lee, author of *The Amphibians and Reptiles of the Yucatán Peninsula*

Amphibians and Reptiles of Baja California, Including Its Pacific Islands and the Islands in the Sea of Cortés

L. LEE GRISMER

FOREWORD BY HARRY W. GREENE

The Baja California peninsula is home to many forms of life found nowhere else on earth. Grismer has produced the most comprehensive work on the herpetofauna of the peninsula and its islands ever published. With its stunning color images, detailed accounts of many little-known species, and descriptions of the region's diverse environment, this is the definitive guide to the amphibians and reptiles of a fascinating and remote region.

"Grismer brings together an impressive amount of original field and laboratory research, supplemented with a thorough review of existing literature, to present a first-rate accounting of the Baja California herpetofauna."

–Robert Hansen, Editor, *Herpetological Review*

UNIVERSITY OF CALIFORNIA PRESS

LIZARD SOCIAL BEHAVIOR

edited by Stanley F. Fox, J. Kelly McCoy, and Troy A. Baird

"This is an original, substantial, and long-needed contribution. The introduction places the subject in context and shows how lizards can provide unique information not readily available through study of other organisms. The book is logically organized, beginning with a focus on individual variation, moving to comparisons between populations, and finishing with species comparisons. Readers with a general interest in social behavior will be drawn to peruse other sections where they will find, as I did, an abundance of additional interesting and informative material."—George A. Middendorf III, Howard University

408 pages, 82 illustrations, $89.95 hardcover

PATTERNS OF DISTRIBUTION OF AMPHIBIANS

A Global Perspective

edited by William E. Duellman

"Anyone with an interest in the distribution and/or abundance of amphibians will find something of value in this remarkable collection of essays."—*Copeia*

"There can be no doubt that is destined to become the standard reference on amphibian zoogeography. It is an impressive book containing a breathtaking wealth of detail, while at the same time encompassing an extraordinarily broad subject area."
—*Herpetological Review*

"*Patterns of Distribution of Amphibians* provides a gateway to the pertinent literature on amphibian distribution for each geographic region of the globe. It should be on the shelves in the herpetology or biogeography section of any academic or research library."
—*Ecoscience*

648 pages, 124 illustrations, $72.95 hardcover

Artwork and Slides Wanted for *HR*

We are always interested in obtaining illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90-mm wide column. Original art, or high quality photocopies, should be packaged to ensure safe delivery and sent to the Editor. Alternatively, we would be pleased to receive material in electronic format; consult the Editor for appropriate file formats and sizes.

Also, we are interested in evaluating outstanding color slides of amphibians and reptiles for possible use on future *HR* covers. When reviewing material for submission, photographers should keep in mind the vertical format of our covers. In addition to highlighting outstanding photography, our cover subjects should lend themselves to communication of biologically interesting information through accompanying text. If you would like to have your work considered, please contact the Editor ***prior*** to sending any slides. We prefer to review images as low-resolution JPEG files before requesting examination of original slides. Postal and e-mail addresses are listed on the inside front cover.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, and Current Research should be sent directly to the appropriate section editor. Send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, Herpetological History, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor or Managing Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Theodora Pinou; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Ecology & Evolutionary Biology, Yale University, P.O. Box 208106, New Haven, Connecticut 06520-8106, USA. Periodical postage rates are paid at New Haven, Connecticut with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Attn. Donald Schmitt, SSAR Membership Office, P.O. Box 253, Marceline, Missouri 64658, USA.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Breck Bartholomew, SSAR Publications Secretary (address and contact numbers on inside front cover) regarding missing or damaged issues.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 740		US $440
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6

A Novel Method for the Extraction and Amplification of DNA from Amphibians

ADAM DAVIS
LESLIE B. SLUSHER*
and
JOHN T. BENESKI
Department of Biology, West Chester University of Pennsylvania
West Chester, Pennsylvania 19383-2130, USA

** Author to whom all correspondence should be addressed:*
e-mail: lslusher@wcupa.edu

Here we describe a simple method for extraction and amplification of DNA from salamanders that neither affects the mortality of live specimens nor jeopardizes rare and endangered populations. We tested the FTA Gene Guard System® (Gibco BRL; Rockville, Maryland) and compared its efficacy for DNA extraction and amplification to that of a more conventional method that relies on fresh tissue. FTA cards (Gibco BRL; Rockville, Maryland) make use of filter paper impregnated with a proprietary formulation for long-term DNA storage and protection. Currently published techniques using FTA cards include extracting DNA from humans (Burgoyne et al. 1997), plants (Lin et. al. 2000), field mice (Higgins et al. 2000), and bacteria (Hansen and Blakesley 1998; Rogers and Burgoyne 1997).

Material and Methods.—Eight salamanders from the family Plethodontidae were sampled using the FTA method of DNA extraction and amplification: *Desmognathus conanti* (Cullman Co., Alabama), *D. fuscus* (Chester Co., Pennsylvania), *D. welteri* (Harlan Co., North Carolina), *Eurycea bislineata* (Chester Co., Pennsylvania and Monroe Co., Pennsylvania), *E. wilderae* (Watauga Co., North Carolina), *Gyrinophilus porphyriticus* (Macon Co., North Carolina), and *Pseudotriton ruber* (Jackson Co., North Carolina). The conventional method of DNA extraction and amplification used tail tissue that was excised from the *D. fuscus* and both the northern and southern Pennsylvania forms of *E. bislineata*. A partial sequence of the mitochondrial 12S rRNA gene was amplified, subcloned, and sequenced from all individuals. The primers used for PCR amplification and DNA sequencing (5'-CAA ACT GGG ATT AGA TAC CCC ACT AT-3'; 5'-TTC CGG TAG ACT TAC CAT GTT ACG-3') and the internal primers used for DNA sequencing (5'-AAG AAA TGG GCT ACA TTT TT-3'; 5'-AAA AAT GTA GCC CAT TTC TT-3') were developed from the previously published sequences of Titus and Larson (1996).

In the conventional method approximately 0.03 g of tail tissue was removed from each specimen, finely minced with a sterile razor blade and added to a 1.5 ml centrifuge tube with 700 µl of DNA extraction buffer (Hedges et al., 1991). All DNA samples were digested with 35 µl of 10 mg/ml Proteinase K at 37°C for 6–10 h, extracted using a standard phenol-chloroform extraction protocol followed by ethanol precipitation, and diluted to 100 ng/µl for PCR. In the FTA method epithelial cells were scraped from the dorsal side of each salamander with a sterile toothpick and transferred to an FTA card. The FTA card was left to dry from 24 h up to several months in a zip-locked plastic bag. A 4 mm disc containing the DNA sample was punched out of the card and deposited into a sterile 0.5 ml microcentrifuge tube. DNA purification was performed according to the manufacturer's protocol using FTA purification reagent (Gibco BRL; Rockville, Maryland) and TE buffer, pH 7.5.

DNA obtained by conventional extraction was amplified in a 100 µl reaction mixture containing 0.5 µM of each primer, 1X PCR reaction buffer, 200 µM dNTPs, 2.5 U Taq Polymerase, 1 ng/µl DNA template, and ddH_2O. The same PCR reaction mixture, minus the 1 ng/µl DNA template, was used to amplify the purified FTA sample. Reactions excluding DNA template were prepared as negative controls. DNA amplification was performed in 30 cycles of denaturation at 94°C for 30 s, annealing at 55°C for 35 s, and extension at 72°C for 150 s, with 4 s added to the extension time per cycle (Titus and Larson 1996). A final cycle was added which had a 7 min extension period at 72°C.

Results and Discussion.—Although DNA yields from the conventional method were higher than those from the FTA method, the PCR products from all preparations were sufficient to successfully clone and subsequently sequence the DNA (Fig. 1). A total of 444 base pairs (bp) were recovered by both the conventional and FTA methods for *Desmognathus fuscus*, 439 bp from the northern Pennsylvania form of *Eurycea bislineata*, and 440 bp from the southern Pennsylvania form of *E. bislineata*. The DNA sequences that were derived using both methods were 100% identical for all three salamanders tested. As for the five additional DNA sequences that were extracted solely by the FTA method,

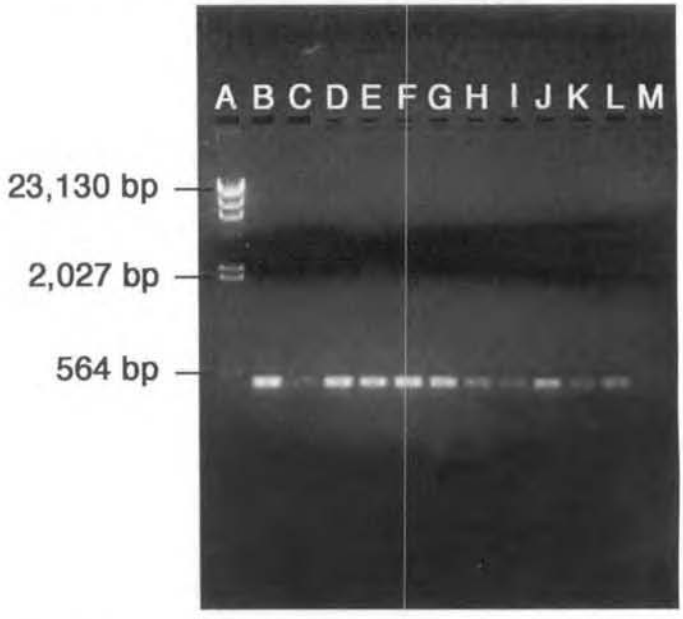

FIG. 1: Comparison of PCR products obtained from conventional (Lanes B, D, and F) versus FTA extraction methods (Lanes C, E, G, H, I, J, and K). One percent agarose gel with 0.02 µg/ml ethidium bromide containing l DNA cut with Hind III (A), salamander PCR products (B–L), and a negative control (M). Numbers on the left side of the agarose gel correspond to fragment sizes in base pairs (bp) of the l DNA ladder. Species sampled include *Desmognathus fuscus* (B and C), the northern Pennsylvania form of *Eurycea bislineata* (D and E), the southern Pennsylvania form of *E. bislineata* (F and G), *D. conanti* (H), *D. welteri* (I), *E. wilderae* (J), *Gyrinophilus porphyriticus* (K), and *Pseudotriton ruber* (L).

441 bp were recovered from *D. conanti*, 443 bp from *D. welteri*, 437 bp from *E. wilderae*, 440 bp from *Gyrinophilus porphyriticus*, and 440 bp from *Pseudotriton ruber*. Sequences recovered from all eight individuals are listed in the Genbank database (www.ncbi.nlm.nih.gov) under accession numbers AF290183–90.

The fact that we obtained identical sequences for the 3 salamanders tested by both methods and that we were able to obtain sequences for the 5 additional specimens using the FTA method demonstrates the effectiveness of FTA cards as a reliable, non-injurious alternative to conventional methods of DNA extraction and amplification from live individuals. Its relatively unintrusive means of collecting DNA templates from amphibians by scraping epithelial cells renders it conducive to large-scale field sampling of rare and endangered species. By carrying a zip-locked plastic bag containing an FTA card, a pair of sterile lab gloves, a sterile toothpick, and a sterile petri dish, researchers can easily collect and store DNA at any opportunity. In addition, the use of FTA cards does not conflict with simultaneous morphological or behavioral analyses by removing tissue, nor does it reduce the value of individuals as potential voucher specimens (Summers et al. 1999). Finally, FTA cards can be shared easily throughout the research community since DNA samples can be transported between laboratories on whole FTA cards or as punched-out 4 mm discs. Given these advantages, the FTA method of DNA extraction and amplification could be a highly beneficial technique for reliably obtaining molecular information without risking the conservation of amphibian species.

Acknowledgments.—We gratefully acknowledge Paul A. Verrell of Washington State University for allowing us to collect epithelial cell samples from his specimens of *Desmognathus conanti*, *D. welteri*, *Eurycea wilderae*, *Gyrinophilus porphyriticus*, and *Pseudotriton ruber*.

The Doubly-Labeled Water Technique is Impractical for Measurement of Field Metabolic Rate in Freshwater Turtles

DAVID T. BOOTH
Department of Zoology and Entomology, The University of Queensland Queensland 4072, Australia
e-mail: DBooth@zen.uq.edu.au

Doubly-labeled water is a powerful method for measuring field metabolic rate in wild animals and has been used numerous times on a diversity of reptiles (Beaupre 1996; Benabib and Congdon 1992; Christian and Green 1994; Christian et al. 1996; Nagy and Shoemaker 1975, 1984; Nagy et al. 1984, 1991; Peterson 1996a; Peterson et al. 1998; Plummer and Congdon 1996; van Marken et al. 1993). The technique uses the difference in rates of loss of isotopically labeled oxygen (usually ^{18}O) and hydrogen (^{2}H or ^{3}H) atoms from body water to estimate carbon dioxide production, providing an indirect measure of metabolic rate (Lifson and McClintock 1966; Nagy 1975, 1980, 1989). The labeled oxygen is lost by two routes: 1) through body water turnover and 2) carbon dioxide lost via respiratory gas exchange, while the labeled hydrogen is only lost via water turnover (see Nagy 1980 and 1989 for a detailed account of theory and experimental errors associated with this technique).

To use this technique, animals need to be caught twice and blood samples taken on both occasions. On the first occasion, total body water is determined by isotope dilution, and the starting blood isotope concentrations established. On the second occasion end isotope concentrations are determined.

There is a trade-off between water and carbon dioxide turnover rates and time between recapture. Ideally the amount of isotope given should be minimal while the period between recapture as long as possible to allow any "abnormal" behavior associated with capture to be "swamped" by normal activity. If turnover rates are so high that the time between release and recapture needs to be less than a day, this technique is not very useful because of the possibility of "abnormal" behavior associated with capture and handling of animals completely obscuring "normal" behavior.

High water turnover rate might also cause isotopically labeled oxygen and hydrogen atoms to reach background levels before a difference in rates of isotope loss can be detected (Congdon et al. 1982; Peterson et al. 1998). Aquatic gill breathing animals such as fish fall into this category because the rate of water turnover is extremely high (Nagy and Peterson 1988). However, aquatic reptiles are air breathers and have an integument that is relatively impermeable to water, so the doubly-labeled water technique should be suitable for these animals. For example this method has been successfully utilized in field studies on marine iguanas (Nagy and Shoemaker 1984), a semi-aquatic lizard (Christian et al. 1996) and a semi-aquatic snake (Peterson et al. 1998). Here I report the feasibility of using the doubly-labeled water method to measure field metabolic rate in two species of freshwater turtle by measuring water turnover rate of these animals in captivity.

Two adult female Brisbane river turtles (*Emydura signata*) and a single adult female broad-shelled river turtle (*Chelodina expansa*)

were captured and held in a 20,000-liter tank exposed to prevailing weather conditions during the Austral summer (December 1998). Turtles were not fed for 5 d prior to and during the measurement periods. Turtles were removed from the water, weighed and injected intra-muscularly into a hind limb with 100 $\mu Ci \cdot ml^{-1}$ tritiated water (HTO), 1.0 ml in *E. signata* and 2.0 ml in *C. expansa*. After a 2 h equilibration period where turtles were held in containers out of water, a 1.0 ml blood sample was taken from the occipital sinus to determine body water volume via isotope dilution (Nagy and Costa 1980) and to determine isotope concentration at the beginning of the measurement period. Two trials were run. In the first (4–7 Dec), turtles were released back into water immediately after the initial blood sample, and a second blood sample taken after 3 d in water. In the second trial (17–20 Dec) turtles were held out of water for 2 d after the initial blood sample was taken. A second blood sample was taken and then the turtles were released into water for 1 d before a third blood sample was taken. Turtles were weighed every time a blood sample was taken. Water was micro-distilled from blood samples (Wood et al. 1975) and the HTO activity of the distillate determined in triplicate by liquid scintillation counting with appropriate blanks and standards. Any mass change between successive blood sampling times (maximum mass change was 70 g) was treated as if it occurred linearly and because of the loss/gain of water, so average water efflux and influx during the experiment were calculated using equations (4) and (6) respectively of Nagy and Costa (1980).

TABLE 1. Body mass, total body water and rate of water influx and efflux of turtles during trial 1. The trial lasted three days and animals were in water continuously during this time. Predicted water flux from allometric equation for reptiles in Nagy and Petersen (1988).

Turtle	Mass (g)	Total Body Water (ml)	Water Content (%)	Water Influx (ml/day)	Water Efflux (ml/day)	Predicted Water Flux (ml/day)
E. signata #1	1703	1014	60	4387	4360	45.3
E. signata #2	1852	1160	63	3308	3317	48.2
C. expansa	3046	1923	63	3268	3296	69.1

TABLE 2. Body mass, total body water, rate of water influx and efflux of turtles during trial 2. The trial lasted three days, the first two days on land, the last day in water. Predicted water flux from allometric equation for reptiles in Nagy and Petersen (1988).

Turtle	Mass (g)	Total Body Water (ml)	Water Content (%)	Water Influx (ml/day)		Water Efflux (ml/day)	Predicted Water Flux (ml/day)
E. signata #1	1822	1141	62	Land	2.2	56.7	47.6
				Water	4930	4890	
E. signata #2	1900	1212	64	Land	3.2	14.6	49.0
				Water	2759	2706	
C. expansa	3090	1973	64	Land	17.0	49.5	69.8
				Water	3223	3220	

Mean water temperature during the trial was 26°C, but water temperature fluctuated daily between 24°C and 28°C. Turtle mass, total body water volume, and water flux rates for trials 1 and 2 are presented in tables 1 and 2, respectively. Water efflux was approximately two orders of magnitude lower when turtles were held out of water compared to when they were in water (Table 2).

Comparison with other species of turtle is complicated by the allometric effect of body size. The most appropriate comparison can be made using an allometric equation for water turnover in reptiles (Nagy and Peterson 1988). Water turnover rates were similar to predicted when turtles were held out of water (Table 2), but two orders of magnitude above predicted when turtles were in water (Tables 1 and 2). Thus turtles turned over their entire body water pool 1.6 to 4.3 times per day when in water. *C. expansa* and *E. signata* do not actively ventilate their cloaca (Priest 1997; personal observation), so it is unlikely that large amounts of water are exchanged with the environment via the cloaca. Assuming that the integument is relatively impermeable to water, turtles must have been drinking and urinating large volumes of water because they did not feed during the measurement period. The reason why these turtles drank so much remains unknown. Except for a study on hatchling diamondback terrapins (*Malaclemys terrapin*; Dunson 1985), water turnover rates of turtles in freshwater have not been reported in the literature. In Dunson's (1985) study the hatchling also had much higher than predicted (4.6 $ml \cdot d^{-1}$ measured verses 0.84 $ml \cdot d^{-1}$ predicted) water turnover rates so very high water turnover rates appear to be typical of freshwater turtles. As such, these extremely high water turnover rates make the doubly-labeled water method impracticable for measuring field metabolic rate in freshwater turtles, a finding foreshadowed by Congdon and coworkers (Congdon et al. 1982).

Acknowledgments.—This study was conducted under The University of Queensland Animal Ethics Approval No. ZOO/275/98/URG. Turtles were collected under Queensland Parks and Wildlife Service permit No. E4/000091/98/SAB. I thank Frank Carrick and Bill Ellis for the tritiated water and use of the scintillation counter.

Collecting frogs in the field can be a very arduous task. Their leaping ability allows them to escape quickly from whatever container in which they are placed. Plastic ziploc bags have been utilized, but they sometimes become awkward to seal, especially if mud gets into the ziploc mechanism. Bags can become expensive as they are not typically reusable. These bags also have the disadvantage in that they easily open, releasing the frogs, and that they are easily squashed because of their flimsy nature. The device described herein allows bulk collection of frogs as well as other amphibians and reptiles, without the time-consuming task of preventing the contained frogs from escaping as new captures are added. A detailed version of the device is described below (Fig. 1).

Construction of this holding chamber requires two plastic or styrofoam cups, a styrofoam ice chest or a styrofoam box (commonly used for shipping tropical fish), and either a pair of tooth-

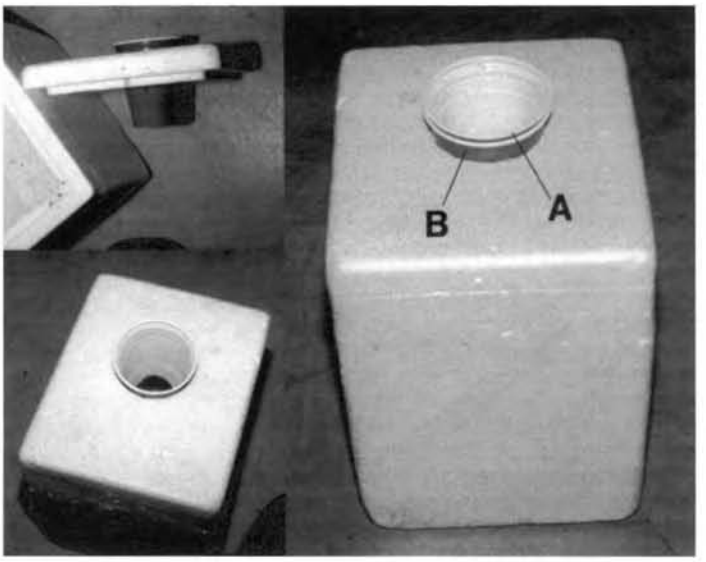

Fig. 1. Design of device for bulk field collection of anurans and other herps. The upper left box shows the position of the cup in the lid. The right hand box shows how the two cups are seated inside each other to prevent the escape of frogs. The lower left box shows the view into the box through which specimens are deposited during collection.

picks or duct tape. First, cut a round hole in the lid of the ice chest so that a plastic cup (Cup B) can be forced into it to about 2/3 of its length. Cut the bottom off the plastic cup and lodge it into the hole. The second intact cup (Cup A) is inserted inside the first cup to close the hole. Toothpicks can be used to hold the lid in place by sticking them through the lid and into the bottom of the box (preferably at a 45° angle to the top). Duct tape can be used instead of toothpicks.

The simplicity of this container is affirmed in its utility as a reservoir for holding large numbers of anurans. Place 2–3 cm of water in the bottom of the box. As each frog is captured, lift Cup A out of Cup B so the frog can be placed into the box. Return Cup A to its original position in Cup B to confine the frog. Cup B will function as a funnel does in a funnel trap (i.e., it keeps the frogs in). Cup A is placed in Cup B to prevent frogs from leaping out, a special problem if treefrogs are being collected.

This device has worked quite well in the field. It is light weight, inexpensive, and can temporarily house a large number of frogs. This "frog box" allows quick collection and secure containment of large numbers of anurans from a single location. The styrofoam insulates specimens from heat, especially if water and/or a small bag of ice is/are placed inside. There are some disadvantages that can be overcome with a little creativity. The device can be bulky if a large-sized version is used. Duct tape tears the styrofoam making it difficult to reuse the frog box. It is not capable of supporting heavy objects stacked on it because of its styrofoam construction. It can also be difficult to retrieve frogs from the device. The difficulty with removing frogs might be alleviated by placing a small plastic garbage bag in the box with the mouth of the bag extending out of the entry hole. A bottomless cup can be inserted in the bag's mouth to hold it open. The addition of the internal bag works, but can cause other problems detracting from the simplicity of this container. We have found that this container alleviates the hassle of opening and closing plastic containers or ziploc bags during inclement weather. Overall, it provides a useful method for temporarily housing frogs as well as other herps in the field.

A Comparison of Two Methods for Estimating the Abundance of Amphibians in Aquatic Habitats

JOSEPH J. WILSON*
and
TIMOTHY J. MARET
Department of Biology, Shippensburg University
Shippensburg, Pennsylvania 17257, USA
e-mail (TJM): tjmare@ship.edu

State College, Pennsylvania 16803, USA
e-mail: jwilson@gfnet.com

Accumulating evidence for the global scope of declines among amphibian populations (Blaustein and Wake 1990; Houlahan et al. 2000) has generated increased interest in their monitoring. Determining whether a particular population is declining or experiencing natural fluctuations requires long-term population studies (Blaustein et al. 1994; Pechmann et al. 1991). Aquatic amphibian populations have been surveyed using a number of methods, including seining, dip netting, trapping, and enclosure sampling (Olson et al. 1997; Shaffer et al. 1994). There are, however, serious limitations to aquatic surveys (Fellers and Freel 1995). For example, sampling methods to determine species presence are often ineffective for estimating abundance or density. Most methods of estimating abundance actually provide an index of number of individuals per unit time or distance (Fellers and Freel 1995; Olson et al. 1997). Furthermore, methods that actually estimate density, such as enclosure sampling (Shaffer et al. 1994), are frequently too cumbersome or impractical for broad application. If a large number of habitats is to be sampled regularly, a method that estimates aquatic amphibian abundance quickly and accurately is clearly needed.

We tested the effectiveness of timed dip net collections for estimating aquatic amphibian abundance by comparing timed collections results to density estimates obtained from "drop box" enclosure sampling. Timed collections require little effort and can be performed in minutes, making them ideal for long-term monitoring of pond-dwelling amphibians. Drop box sampling, on the other hand, is cumbersome and often takes well over an hour per sampling event (Maret, pers. obs.).

We sampled nine temporary ponds in the Michaux State Forest (Franklin County, Pennsylvania) twice during June 1999 using both drop box sampling and timed dip net collection (Sampling event 1: timed dip net collection on June 1, drop box sampling on June 2–4; Sampling event 2: drop box sampling on 16 June, time dip net collection on 21 June). On each of the two occasions, sampling with each method took place within five days of each other and was performed by the same individuals. Four of the ponds dried between the two sampling dates so only five ponds were sampled during the second interval. Six species were sampled during the study: larval *Ambystoma maculatum* (spotted salamanders); *A. jeffersonianum* (Jefferson salamanders); *A. opacum* (marbled salamanders); *Rana sylvatica* (wood frogs); and *Pseudacris crucifer* (spring peepers), and adult *Notophthalmus viridescens* (red-spotted newts). The pond habitats sampled varied considerably, from heavily shaded ponds with leaf litter and woody debris to open ponds with herbaceous and some woody vegetation.

The drop box sampler was constructed of 1/8 inch plexiglass, enclosed a surface area of 0.49 m^2 (0.7 m x 0.7 m), and was 0.75 m high. Marks on the side of the box were used to gauge water depth. We attempted to drop the box at evenly spaced sample locations along 2 or more (depending on pond size and shape) straight transects across each pond, but scattered woody debris occasionally caused us to deviate from this alignment. The number of drops ranged from 2 in a pond that had dried to a small puddle to 10–12 in the larger ponds (the largest pond surveyed covered an area of approximately 1096 m^2). Once the box was dropped at a location, the bottom edges were quickly pressed into the sediment to prevent animals from escaping. The inside of the box was thoroughly swept with a dip net (1/8 inch mesh) to collect amphibians trapped within the box. Dip net sweeps continued until no animals were collected in three successive sweeps. Amphibians were identified and released back into the ponds. Water depth was determined in order to calculate water volume within the box so that amphibian density (per m^3) could be calculated. Drop box sampling was con-

TABLE 1. Density (DENS) and catch/person/minute (CPM) estimates of amphibians from aquatic habitats in south-central Pennsylvania sampled by two methods. Density was determined using the drop box method and is reported as number/m^3. Four ponds dried before the second sampling event.

ducted by the same person on both sampling occasions (once the box was in place, two other people helped with the dip net sweeps)

Long-handled dip nets (16 inches wide x 12 inches high x 12 inches deep, 1/8 inch mesh) were used for the timed dip net collections. Three people sampled each pond by dividing the pond roughly into thirds, wading into the water, and dip netting all microhabitats. Sampling lasted from three to five minutes depending on the size of the pond. Generally, ponds less than 300 m^2 were sampled for three minutes while ponds greater than 300 m^2 were sampled for five minutes. Sampling ceased after five minutes at which time specimens were sorted by species and counted. Results were converted to catch/person/minute. If more than one hundred individuals were caught of a species (which only occurred with *R. sylvatica*), counting stopped at one hundred individuals. Timed collections were performed by the same three people on both sampling occasions.

We used a standard statistics package (SPSS Inc. 1999) to compare catch per unit effort measures from dip net sampling with density estimates from drop box sampling. Spearman's rank correlation coefficients (two-tailed) were determined for each sampling occasion and for both sampling occasions combined, using abundance estimates of each species from each pond as observations.

Six amphibian species were collected (Table 1). Red-spotted newts (*Notophthalmus viridescens*) were captured as adults while other species were represented as larvae. High scores from timed dip net collections generally corresponded with high density estimates from drop box samples. In 10 of 84 samples, a species was detected during drop box sampling but not during timed dip net collection. Species tended to be absent from timed collections and present in drop box samples when ponds contained diverse microhabitats, including areas of dense vegetation and woody debris (the absence of *A. opacum* from timed collections at ponds 1 and 2 during the second sampling event is most likely because of larvae metamorphosing and leaving the ponds prior to the timed dip net collection). For this reason, we attribute much of this discrepancy between sampling methods to habitat heterogeneity, and recommend that ponds with complex habitats be sampled more intensively, especially when performing timed collections. Pond heterogeneity also might interfere with drop box sampling and therefore may affect density estimates. Woody debris and dense vegetation are difficult to sample and species might be underrepresented in samples from complex habitats. In 8 of the 84 samples, a species was detected during the timed dip net collection but not during drop box sampling. In all of these samples, catch/person/minute was very low, indicating that the density of the species was most likely also low. This suggests that collection by dip net might be more likely to detect rare species than drop box sampling.

Measures of abundance from dip net sampling were closely correlated with density estimates (Sampling event 1: N = 54 samples [9 ponds x 6 species], Spearman's rho = 0.724, $p < 0.01$; Sampling event 2: N = 30 [4 ponds dried and were not sampled], Spearman's rho = 0.804, $p < 0.01$; Combined events 1 and 2: N = 84, Spearman's rho = 0.729, $p < 0.01$). Timed dip net collections seem to provide relatively reliable estimates of aquatic amphibian abundances. In addition, timed collections were performed in less than one tenth the time needed to perform the drop box surveys. During the first sampling event it took three days to sample nine ponds using the drop box method and less than one day to sample by timed collections. Ponds had dried considerably by the second event; drop box sampling of five ponds took approximately eight hours while the timed collections were concluded in less than one hour (another disadvantage of drop box sampling is that it involves carrying the large and heavy box between sampling locations, which might be difficult if sampling remote locations).

A rapid yet accurate means to quantify aquatic amphibian abundance is needed for effective long-term monitoring of this taxon. Timed collections seem to be an appropriate method for long-term monitoring programs because they are rapid, yield reasonably accurate representations of species abundances, and can be performed easily with minimal equipment. Combining timed collections with a method of estimating density, as we have done with our drop box sampling, allows conversion of catch per unit effort values into estimates of density. Both methods might yield inaccurate results in complex habitats because of difficulty in sampling all habitats. Adopting the timed collection sampling method into amphibian monitoring programs should allow researchers to monitor a larger number of habitats while maintaining a relatively high certainty that abundance estimates are reasonably accurate.

Acknowledgments.—We thank Philip Hayes and Neil Bossart for help in conducting the surveys. Support was provided by the Shippensburg University Graduate Research Program to J. J. Wilson and by the Pennsylvania Wild Resources Conservation Fund to T. J. Maret. Research permits were granted by the Pennsylvania Fish and Boat Commission and Pennsylvania Bureau of Forestry.

The measure of body temperature in ectothermic species is essential to studies investigating behavioral and physiological thermoregulation. Cloacal thermocouples have been used successfully to measure body temperatures (T_b) in a wide variety of species, including frogs, salamanders, turtles, lizards, and snakes (e.g., Cothran and Hutchison 1979; Erskine and Hutchison 1981; Hutchison et al. 1979; Lutterschmidt et al. 1997; Sievert and Poore 1995; Tu and Hutchison 1994). In addition, the combination of thermocouples and data acquisition systems (e.g., Omega OM-550 data logger, Omega Engineering, Stamford, Connecticut) has allowed for the measurement of T_b over extended periods of time without disturbing the animal's activity.

Continuous measures of T_b are typically obtained by inserting and taping a variable- gauge copper-constantan nylon-coated thermocouple 3–4 cm into the cloaca of an animal. A thermocouple-equipped animal may then be placed in a laboratory thermal gradient (e.g., Lutterschmidt 1991) for study of behavioral thermoregulation. Thermocouples must be long enough to reach each end of a linear thermal gradient from a centrally-located fixed point where the thermocouple is connected to a data logger. This length ensures that an animal may have full access to all areas along the length of the gradient. Unfortunately, excess thermocouple wire commonly becomes tangled as the animal moves back and forth along the gradient. We found this to be especially problematic when studying snake species, as they are capable of very unique body movements as compared to other amphibians and reptiles. Once large knots have been placed in the thermocouple, the thermocouple's length is reduced, thus restricting the movement of the animal within the gradient and preventing the animal from thermoregulating. Unlike the problems associated with small snakes, whose movements are restricted by the tangled and shortened thermocouple, larger and stronger snakes often pull their thermocouples from their cloaca. In addition to these problems, thermocouples that are tangled repeatedly are much more likely to break, preventing the collection of T_b by the data acquisition system. Breaks in wires covered by the thermocouple's insulation often go undetected until the downloading of a data file.

We have described common problems associated with the use and tangling of thermocouples and offer a few inexpensive suggestions and modifications to help 1) reduce the occurrence of

thermocouple tangling and 2) prevent animals from easily removing thermocouples from their cloaca. Details on the basic function and making of copper-constantan thermocouples have been described and may be found elsewhere (e.g., Omega Engineering, Inc. 1998).

Thermocouple Coiling.—One method used to aid in reducing thermocouple tangling was described by Tu and Hutchison (1994). They also observed that straight thermocouple wires tangled easily and were often broken by snakes. Thus, thermocouples were reshaped into a long spiral or spring-like coil by tightly coiling it around a glass rod or pipette and taping it in place. The coil was then placed in a boiling water bath for approximately 30 min and then quickly immersed in an ice bath. The heating, softening, and then sudden cooling of the thermocouple's nylon insulation reshaped the straight thermocouple into a spring-like coil. Although we found this method useful in our studies (Lutterschmidt et al. 1997; Lutterschmidt et al. 1998), it is not without difficulties. Firstly, the coiling of thermocouples works well for small-gauge thermocouple wire. Larger-gauged (i.e., thinner) thermocouple wire easily stretches and does not retain its spiral or spring-like coiling because of its thinner insulation. Secondly, the coiling of smaller-gauged (i.e., thicker) thermocouple wire is suited best for larger snakes (≥ 200 g), as smaller-bodied snakes are not strong enough to stretch the coil to gain access to the ends of the thermal gradient. Thirdly, although coiled thermocouples seem to work well with the more passive thermoregulatory movements of water snakes (*Nerodia rhombifer*), they were disastrous when used with bullsnakes (*Pituophis melanoleucus*). The greater activity and climbing-like movements of *P. melanoleucus* created very restrictive tangles in the thermocouple wire, which were nearly impossible to untangle (as one with experience in attempting to untangle a Slinky® would concur).

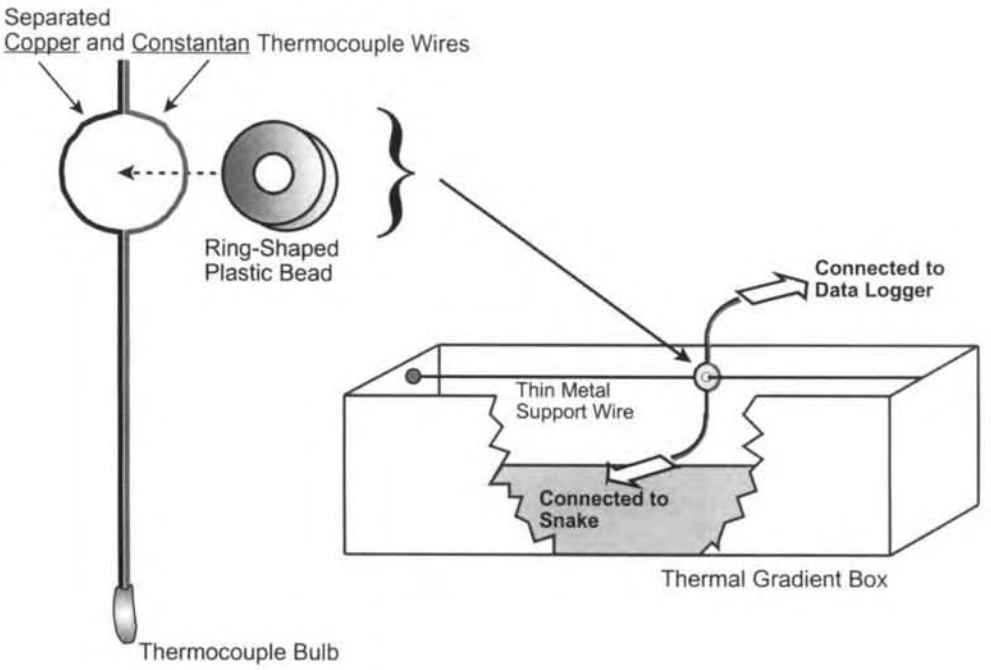

FIG. 1. Illustration of the thermocouple hanging-support system showing the placement of the ring-shaped bead in the thermocouple and the hanging-support wire in the linear thermal gradient box.

Thermocouple Hanging-Support System.—This alternate method reduces the occurrence of thermocouple tangling by keeping the thermocouple from resting entirely on the floor of the thermal gradient. We first separated the copper and constantan wires approximately 50 cm from the thermocouple's bulb-end using a scalpel, being careful not to damage the insulation covering the copper and constantan wires. This 50 cm length was used because it was slightly longer than the diagonal distance from the support wire to the edge of the gradient floor, ensuring complete access to all areas of the gradient's substrate. Once the copper and constantan wires were separated, we used epoxy to secure each wire to either side of a small ring-shaped plastic bead. Once the epoxy had set, we threaded the ring-shaped bead onto a thin metal wire, which was tightly strung across the length of the gradient (ca. 35 cm above the gradient floor) by two tension screws (Fig. 1). Possible friction and drag between the bead and wire was reduced by applying lubricant to the wire.

We tested and used this system in studying the thermoregulation of the Woodhouse's Toad (*Bufo woodhousii*) and the African House Snake (*Lamprophis fuliginosus*). This thermocouple hanging-support system worked extremely well in keeping excess thermocouple wire from dragging on the gradient floor. A few individuals of *L. fuliginosus* had a tendency to climb onto the hanging-support wire. One might want to further consider this possible problem when testing more arboreal snake species. Although we have limited data on skinks (*Eumeces*), we expect this system to work well with most non-arboreal species.

Thermocouple Duct-Tape Patches.—The problems associated with individuals pulling out their thermocouples result primarily from the methods used to secure a thermocouple to an animal. Thermocouple wires have a small surface area, and therefore only a very small proportion of the thermocouple wire actually contacts the tape's adhesive. Thus, within a few hours, the secured thermocouple loosens from the tape used to attach it to the study animal. Normal tension placed on the thermocouple from an animal's movement in the gradient can then cause the thermocouple to be pulled from the cloaca, even though the tape used to secure the thermocouple is often still attached securely to the animal. This problem might be solved by using a strong-adhesive tape rather than a medical tape (e.g., 3M-brand Nexcare® waterproof adhesive tape) to ensure attachment of the thermocouple. However, a strong-adhesive tape would be difficult to remove and could damage the scales and skin of the animal.

These problems were solved by placing a small patch of strong-adhesive duct tape around the thermocouple. This patch was placed ca. 5–6 cm from the bulb-end of the thermocouple. This patch increased the surface area of the thermocouple to be taped and

secured to the animal with the 3M-brand Nexcare® tape. The duct-tape patch was made from a piece of duct tape measuring approximately 7 cm in length and 5 cm in width (i.e., width of the duct tape) for use with snakes having a snout-vent length of approximately 60 cm and a body mass of 100 g. The thermocouple wire was placed perpendicular to the tape's length and attached to the piece of duct tape with the adhesive side facing upward. The sides of the duct tape were then folded over the thermocouple in a tri-fold fashion so that the duct tape's strong adhesive was not exposed (Fig. 2a). This patch now measured 5 cm (tape's original width) along the length of the thermocouple and was approximately 2–3 cm wide after tri-folding over the ends. The patch of duct tape would now securely hold the thermocouple because 1) the duct-tape adhesive in contact with the thermocouple is much stronger than the 3M-brand Nexcare® waterproof adhesive tape used to attach the thermocouple to the snake, 2) the strong adhesive of the duct tape covers both sides of a 5 cm length of the thermocouple, and 3) this duct-tape patch creates a larger surface area to be attached to the animal with the Nexcare® tape. The finished duct-tape patch should be wide enough to cover the ventral scales of the snake just anterior to the vent, leaving many of the dorsal scales exposed for contact with the Nexcare® tape's adhesive.

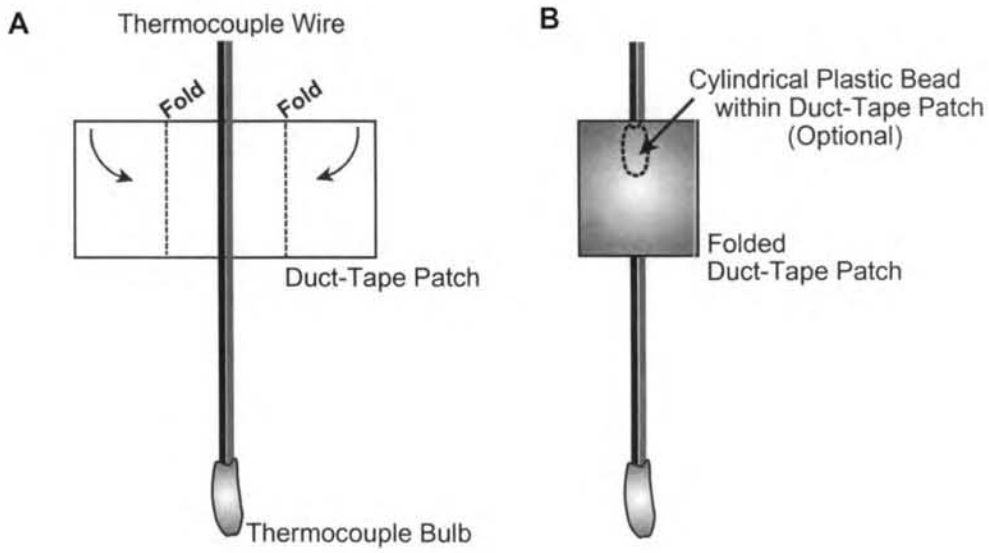

FIG. 2. Illustration of the (a) attachment of a duct-tape patch to a thermocouple and (b) the placement of the cylindrical plastic bead within the duct-tape patch.

An additional modification can be used to help prevent the occasional thermocouple from sliding within the duct-tape patch. We threaded a small and thin cylindrical plastic bead (ca. 1 cm in length) onto the thermocouple wire. We suggest a bead that slides snugly over the thermocouple for a secure fit. The bead must be threaded onto the thermocouple prior to making the temperature-sensing bulb-end of the thermocouple. The bead was further secured to the thermocouple with epoxy 5–6 cm above the bulb-end of the thermocouple; the duct-tape patch was placed over the bead (Fig. 2b). This bead may further prevent a thermocouple from being pulled through the duct-tape patch.

The combination of the plastic bead and the surface area of the duct-tape patch provided a secure attachment of the thermocouple to the animal which remained in place for at least 36 h while monitoring the thermoregulatory behavior of *P. melanoleucus*. We have tested similar versions of these modified thermocouples with skinks (*Eumeces*), juvenile *Alligator mississippiensis*, and sunbeam snakes (*Xenopeltis*). We do not recommend the use of these methods for securing thermocouples to amphibians; methods for attaching thermocouples to toads have been described by Sievert and Poore (1995). We hope that these described modifications to the basic thermocouple will prove quite useful to experimenters studying the thermoregulatory behavior of ectotherms in the laboratory.

Acknowledgments.—Related work was supported in part by a Pennsylvania Academy of Science Research Grant, a Graduate Student Senate Research Grant from the University of Oklahoma, and funding from the Department of Zoology at the University of Oklahoma. Body temperatures of turtles and tortoises have been measured using mercury-in-glass thermometers (e.g., Hillard 1996; Woodbury and Hardy 1948), temperature-reporting transmitters attached to the surface of the animal (Zimmerman et al. 1994), and implanted (or swallowed) devices to measure internal-body temperatures (e.g., Marlow 1979; Sajwaj 1998; Zimmerman et al. 1994). Samples of body temperatures have been used to describe the range of body temperatures available to individuals under a variety of environmental conditions (e.g., Christian and Tracy 1985; Hillard 1996; Zimmerman et al. 1994). Profiles of body temperatures require repeated measurements on each animal, but those measurements can be time consuming and might cause disturbance to the animal measured (Sajwaj and Lang 2000).

Here, we describe the use of an externally mounted thermistor and datalogger to obtain data on temperatures of terrestrial chelonians at many temporal scales. We describe a location on the body to measure a body temperature closely approximating cloacal temperature. Use of this instrument does not require frequent handling or disturbance to the animal, and does not interfere with natural behavior including mating and egg deposition (Nussear et al., unpubl. data).

We used StowAway™ TidbiT™ temperature dataloggers (Onset Computer Corporation, Pocasset, Massachusetts), customized by Onset from their standard design (TBICU108, –20°C to +70°C). Our datalogger had a weather-resistant thermistor on a 150 mm wire mounted external to the instrument, and no protective coating on the datalogger. The dataloggers were 25 mm in diameter, 14 mm thick and weighed approximately 11 g. Data from the dataloggers were retrieved via an infrared (IR) interface (Optic Base Station-DSA, Onset Computer Corporation, Pocasset, Massachusetts).

Each instrument was calibrated in a water bath against a high-resolution mercury-in-glass thermometer. A thin layer of silicone sealant was applied to the entire exterior surface of the datalogger, which was then coated with dental acrylic (Coralite Duz-All™ acrylic, Bosworth Co., Skokie, Illinois). The coated datalogger weighed 16 g. After coating, we re-calibrated each datalogger and covered it with a circular polyvinyl chloride (PVC) cap (Fig. 1A) before attaching it to the animal. The PVC cap was 32 mm in diameter and 15 mm high (Part # 9745, Shepherd Hardware Products, INC., Three Oaks, Michigan), with holes cut for the IR interface and the thermistor wire (Fig. 1B and C). The IR interface hole was covered with transparent acetate, which allowed for programming and downloading the datalogger without removing the PVC cap or the acetate. Additionally the PVC cap ensured that the optical interface was protected from the environment (Fig. 1D). Silicone sealant and epoxy secured the datalogger to the carapace, and quick-setting glue (Super Glue, Via-Chem INC., St. Laurent, Quebec Canada) followed by a layer of silicone secured the thermistor to the animal.

Our first experiment was to determine an external location for the thermistor probe that best approximated cloacal temperature. While cloacal temperature can differ from temperatures at other locations on the body, this measurement of temperature is reported frequently in the literature (Hailey and Loveridge 1998; Hillard 1996; Woodbury and Hardy 1948) and was suitable for addressing other research questions on body temperature and ecology of this animal. We attached the thermistors (Fig. 1F) of five dataloggers to a single desert tortoise (*Gopherus agassizii*) at the following locations: (1) above the tail (glued to the skin and the shell at the junction of the tail and caudal scute Fig. 1G), (2) left axillary region, (3) junction of the neck and clavicle region, (4) right inguinal region, and (5) in the cloaca (2–3 cm deep). The tortoise was placed in an aquarium (30 x 60 x 40 cm) in an indoor laboratory under a 150 W flood lamp and was heated for one hour. The dataloggers recorded temperatures at one-minute intervals.

In this experiment the temperatures measured above the tail were the least different from cloacal temperature relative to the four external locations measured (Fig. 2). Additionally, the location above the tail was the only location at which the thermistor re-

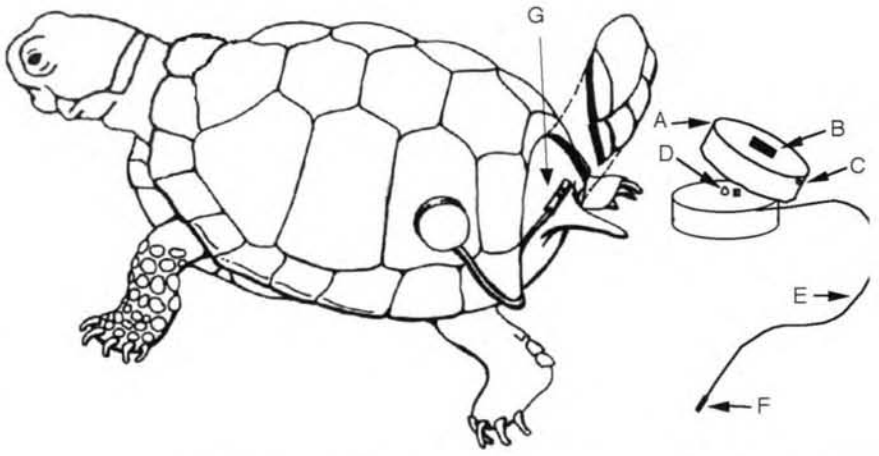

FIG. 1. A schematic of a tortoise showing the datalogger with, (A) PVC protective cap with holes (B, C) cut for the (D) IR interface and (E) thermistor wire, (F) thermistor, and (G) site for thermistor attachment above tail.

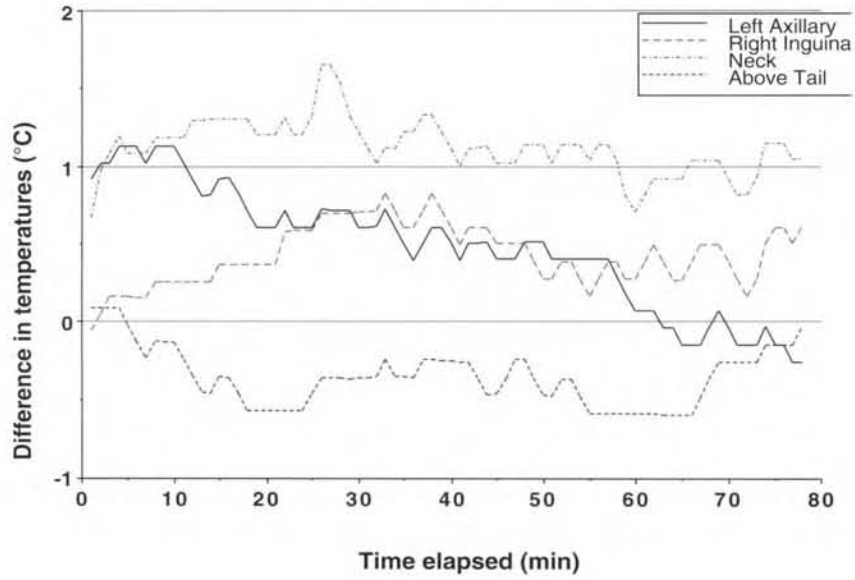

FIG. 2. Temperature differences for four locations on the body of one tortoise as compared to the cloaca during heating for a one hour time period.

mained attached to the tortoise for more than a few days. This is probably because the thermistors at the three other sites were on skin that is moveable (and therefore flexible), and that is regularly shed. We found that areas such as the neck and shoulders provided very short-term attachment sites, which was undesirable for a field study. In contrast, the thermistor above the tail was still attached after four weeks on this animal. Thus, the above-tail attachment point was chosen for subsequent data collection.

Our second experiment was conducted to replicate the correspondence of externally measured temperature to cloacal temperature found in the first experiment, among different animals. We measured body temperatures on six individuals subjected to a broad range of environmental temperatures. The tortoises ranged in length from 99 to 236 mm carapace length (CL), (mean = 169), and in mass from 273 to 2428 g (mean = 1148). A single datalogger was attached to each animal with the thermistor attached above the tail as described above. Tortoises were moved from room temperature (ca. 22°C) into a constant temperature cabinet at 12°C. After cooling, the tortoises were moved to a galvanized metal trough (1.8 x 0.6 x 0.3 m) with eight 150 W flood lamps mounted 40 cm overhead. The floor of the trough was covered with 2 cm of silica sand. This influx of radiant energy created sand surface temperatures of ca. 65°C. Cloacal and esophageal temperature were measured (at 3 and 5cm deep, respectively) after 25 min, and approximately every 10 minutes thereafter using a hand held thermocouple reader (Omega 871A digital thermometer, OMEGA Engineering INC., Stamford, Connecticut). The dataloggers recorded above-tail temperatures once each minute.

In this second experiment the difference between the above-tail temperature and cloacal temperature was greatest (as high as 6°C; mean = 4.4°C) when the animals were warming (Fig. 3). This difference was as low as 2.4°C as the animals approached a body temperature of 35°C. A similar pattern occurred in the difference between esophageal and cloacal temperature (Fig. 3). The time to reach the greatest temperature difference between the cloaca and the esophagus was longer in this case (36 min) with maximum a difference of 3.75°C (mean = 1.96) that later narrowed to 0.68°C.

The datalogger described facilitates automated collection of body temperatures, which can provide more information with less work than other methods (Vitt and Sartorius 1999). For example, using this instrument, researchers can record the body temperatures of many tortoises simultaneously and at a myriad of temporal scales: from fractions of seconds or minute-to-minute measures that can enhance our understanding of physiology and microhabitat selection, to long-term data that can yield information such as the timing of the onset of hibernation and the recurrence of activity in the spring. Temperatures measured above the tail corresponded well with cloacal temperatures (Fig. 2). The thermistors located at other possible attachment sites on the animal did not stay affixed to the animal. Thus, the alternate attachment sites other than above the tail would probably not work well in the field.

The correspondence between external temperature and cloacal temperature can be obscured by differential dynamics in temperatures of body parts during rapid heating or cooling of the animal (Sturbaum and Riedesel 1977; Zimmerman et al. 1992). Under extreme heating conditions, both tail and esophageal temperatures differed from cloacal temperature (Fig. 3). Nonetheless, temperatures above the tail yielded estimates of cloacal temperature with accuracy comparable to that presented by Zimmerman et al. (1992) for temperatures taken from the skin in the scapular region of tortoises. We interpret the discrepancy between cloacal temperature and temperatures measured at different locations on the body as evidence of thermal heterogeneity within

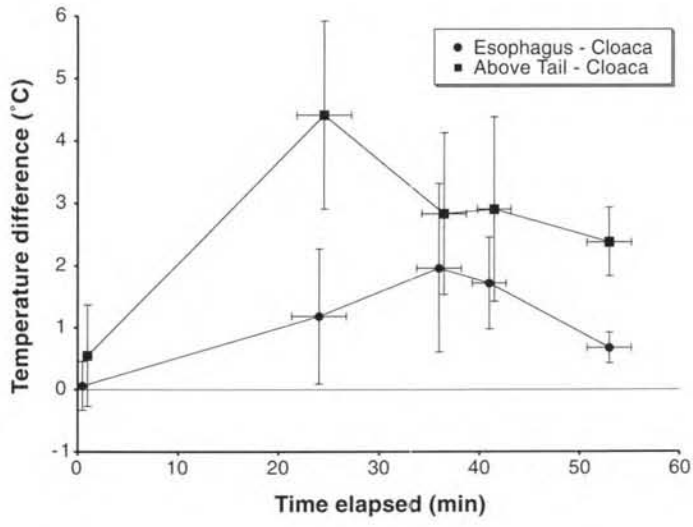

FIG. 3. Temperature differences between above-tail and esophageal temperatures on six tortoises as compared to the cloaca during heating for a one hour time period. Error bars represent the standard deviation of each mean. Horizontal error bars represent the standard deviation of the average measurement time.

the body in this large ectothermic vertebrate, rather than a technological limitation. This in turn raises new questions "is there a single meaningful body temperature in these organisms, and if so, is that meaningful temperature that of the cloaca?" and "to what temperature do tortoises respond when they are in a thermal transient and there are large gradients of temperature within the body?"

Acknowledgments.—The authors complied with Animal Care guidelines at the University of Nevada, Reno, and required state and federal permits were obtained for the work reported here. We thank R. E. Using Masks to Monitor Oxygen Consumption and Breathing Rates of Snakes

CHARLES R. BLEM
and
LAURENCE G. MENDOZA
Department of Biology, Virginia Commonwealth University

e-mail (CRB): cblem@saturn.vcu.edu

The measurement of respiration has been an important facet of the study of vertebrate energetics for several decades (Lillywhite 1987). Traditionally, oxygen consumption has been measured using animals tested in respiratory chambers such as a 3.7-L paint can or other enclosure. Such chambers are useful because they are simple to make and because they provide the ability to exclude environmental factors other than ambient temperature (e.g., light, noise). However, such chambers also prevent study of the effects of these same factors, are not conducive to study of costs of locomotion, and often are not extremely sensitive to short-term changes in metabolic rates. Some researchers have used light-weight, clear plastic masks to overcome these difficulties (e.g., see Gessaman 1987). These allow inhalation of fresh air and collect the gases that are exhaled. Measurement of respiration of snakes by means of masks has been done (Walton et al. 1990), but appears to be rare. Herein we present a critique of two problems potentially associated with measurement of respiration in masked snakes (i.e., effects of stress and failure to include measurement of cutaneous gas exchange) and illustrate some advantages of such techniques.

Materials and Methods.—Brown water snakes (*Nerodia taxispilota*) used in these studies were collected by hand near the confluence of the Appomattox and James rivers, near Hopewell, Virginia, during September 1996, April 1998, and September 1998. The area includes large areas of tidal swamp and marshland. For details about the habitat, see Blem (1981) and Blem and Blem (1990a, 1995). Snakes were kept in groups of 3–4 in glass aquaria 120 x 60 x 60 cm deep in the laboratory for at least three weeks of thermal acclimation at a photoperiod of 12L:12D before the initiation of measurements. They were provided whole small fish (*Fundulus* sp.) and water *ad libitum*. Snakes were not fed for two weeks before each measurement in order to assure that all determinations were being made under post-absorptive conditions.

Oxygen consumption was measured by open-flow respirometry at 12, 17, 22, 27, and 32°C using snakes acclimated for more than two weeks to each of these temperatures (see Blem and Blem 1990b; Blem and Killeen 1993, for details). Oxygen consumption of each snake was measured twice: once in a respirometry chamber and once with a mask. The order of test procedures was determined at random, and the interval between the paired tests was never more than two days. Measurements were made for 15 min after levels of oxygen consumption remained stable for at least 10 min. In chamber tests, air was pulled through a 3.7-L respirometer at 200–500 ml/min, depending upon temperature and mass of individual snakes. An Applied Electrochemistry SR 3-A/I oxygen analyzer interfaced to a personal computer with Sable Systems software was used to make measurements of oxygen consump-

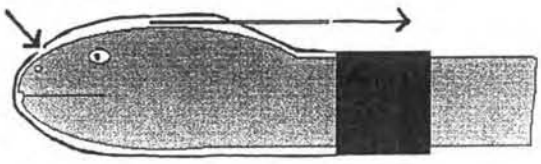

FIG. 1. Mask used in respiration measurements. Arrows indicate direction of air flow.

tion throughout all experiments. Carbon dioxide production was monitored by means of a Beckman 864 infrared CO_2 analyzer. An arrangement of respirometer, flow meter, and pump was used that provided measurements that were independent of the respiratory quotient (Withers 1977; also see Blem and Blem 1990b).

In mask tests, snakes were fitted with 50-ml masks (Fig. 1) generally resembling those used in avian studies (see Gessaman 1987; Walton et al. 1990; Withers 1977). These were constructed of light plastic vials with incurrent ports near the snake's nares. The masks were fastened over the snake's head either with tape or with a small rubber spacer. This did not visibly disturb snakes for more than a few minutes. Outside air was drawn through the mask at a constant rate of 100–300 ml/min by means of thin plastic tubing attached to the posterior end of the mask (Fig. 1). Incurrent openings were slightly larger than the tubing to avoid creating a negative pressure in the mask. In a separate set of tests, rates of inspiration/expiration in masks were determined by using the open-flow system described above, except that flow rates were adjusted in some instances so that individual breaths could be recorded.

All computations of metabolism were done according to Withers' equation 4a (1977). All data sets were tested for normality by means of the Shapiro-Wilk statistic, (SAS 1992; PROC UNIVARIATE), and variances were tested for homogeneity by means of Bartlett's test (Zar 1999). All comparisons of test groups were made by means of paired t-tests.

Results and Discussion.—There are two primary problems potentially associated with use of masks in respiration measurements of snakes. First, one must be sure that masks do not stress test animals so as to cause abnormally high levels of respiration. Brown water snakes became accustomed to masks with repeated tests, but one should be sure to handle the snake carefully and gently while putting the mask in place. Second, because chambers enclose the entire snake and masks do not enclose the body, cutaneous respiration is not being measured and determinations made with masks might therefore be lower than true values. With regard to both problems, none of the mask measurements differed significantly from chamber measurements (Table 1), but chamber values generally were 1–3.9% higher than those recorded with masks. The magnitude of the difference between mask and chamber levels seemed to be a function, at least in part, of test temperature. This probably is because mask measurements do not include respiration through the skin, which can amount to about 8% of total respiration of terrestrial reptiles (Walton et al. 1990) and might be greater when metabolic rates are increased at higher ambient temperatures. The relatively low magnitude of the differences indicates that mask measurements are reasonable approximations of metabolic levels of whole animals. However, respiration through the skin may vary taxonomically, particularly among snakes with different habitats (e.g., aquatic vs terrestrial or desert). This could lead to varying differences between mask and chamber results.

Use of masks can provide a means for measuring energetic costs of ophidian activity (Bennet 1982; Walton et al. 1990). Furthermore, costs of relatively minor factors such as visual or tactile disturbance can be evaluated using clear masks. At rest, mask measurements provide very rapid response times because of the relatively small volume of the mask relative to a respirometry chamber. In fact, one should choose materials in such a way as to minimize both mask weight and volume. There are numerous plastic containers (e.g., centrifuge tubes, vials, or other containers) suitable for this purpose. Only simple modification needs to be done. A hole should be drilled near the tip of the nose to provide an opening for incurrent gas and small-diameter (2–3 mm inside diameter) plastic tubing should be attached near the rear of the mask to carry away the sample gas (Fig. 1). The mask need not be airtight, so long as the oxygen content of surrounding air is known and air is continuously drawn through the mask (see Gessaman 1987).

Under optimal conditions, individual respiration cycles can be recorded (Figs. 2A, 2B). The precision of these is dependent upon: (1) flow rate, which can easily be adjusted to produce results such as those illustrated here, and (2) the rate at which measurements are recorded on the computer. Software can be adjusted to record at very small time intervals (e.g., < 0.01 s) and large files can be accumulated. Care must be taken to adjust flow rates to avoid abnormal (triphasic) respiration typical of excited animals (Clark et al. 1978; Gans and Clark 1978). The actual rate must be determined experimentally and will depend upon the species and size of the snake. Segments of these can be selected, analyzed, adjusted, or deleted. Measurements can also be extended over many hours, although desiccation of the test animal is a concern. This provides opportunity for study of a variety of responses, including respiration rates during locomotion (Walton et al. 1990) or during various behaviors (Blem and Killeen 1993). For example, individual brown water snakes appear to hold their breaths when disturbed (Fig. 2C). This response was observed in all ten snakes tested. The duration of breath holding seems to be independent of body size

TABLE 1. Body mass (g) and respiration rates (ml O_2/h) of brown water snakes measured with a face mask and in a respirometry chamber. N is number of individual snakes. P values are for paired-t tests comparing measurements made using masks with those made in chambers.

Temperature (°C)	N	Mass	Mask	Chamber	P
12	21	265.7 ± 13.7	4.3 ± 0.3	4.4 ± 0.3	0.58
17	17	248.3 ± 13.6	6.4 ± 0.7	6.4 ± 0.8	0.89
22	16	254.3 ± 14.2	10.4 ± 1.3	10.5 ± 1.2	0.49
27	15	259.1 ± 15.6	14.1 ± 1.9	14.3 ± 1.8	0.59
32	15	258.9 ± 15.8	18.1 ± 2.2	18.8 ± 2.1	0.06

and therefore may represent some sort of death-feigning, but this needs more study. Such behavior cannot be tested in closed chambers.

Acknowledgments.—We thank Markino Gamble for measuring respiration rates of snakes in the laboratory. Tom Thorp and Leann Blem assisted in collecting snakes for these studies. Leann Blem, Tom Thorp, and Dan Dombrowski helped in making lab measurements. Funds from the Virginia Equipment Trust and the Virginia Commonwealth University Department of Biology made the study possible. We are grateful to Leann Blem for reading, revising, and correcting an earlier version of this paper. All collecting in this study was carried out with appropriate permissions and state permits and all experimental protocols were done in accordance with rules of the Virginia Commonwealth University animal care committee and NIH principles of animal care.

A Cage System for Maintaining Small Treefrogs

CRAIG S. IVANYI
and
STÉPHANE POULIN
Herpetology Department, Arizona-Sonora Desert Museum
2021 North Kinney Road, Tucson, Arizona 85743, USA

Captive amphibians can be housed in a variety of ways. Often they are maintained in small glass aquaria that are set up as aquatic or semi-aquatic terraria (depending upon the species' habits). There are pros and cons of using such aquaria. On the up side are their low cost and the commercial availability of a variety of sizes. However, the downside is ease of breakage, lack of drains, and the need for modifications to use them for different types of amphibians. For over 4 decades, this type of enclosure was used to house almost all species of amphibians (about 30 species of toads, spadefoots, true frogs, treefrogs and salamanders) maintained at the Arizona-Sonora Desert Museum. After the construction of a new herpetological holding facility, we devised a new type of cage system for small treefrogs.

The system consists of four 40 cm square, polyethylene frame boxes constructed of 20 mm square framing sticks screened with 4 mm high-density, polyethylene mesh (Fig. 1). The mesh is secured by a thin strip of polyethylene that is stapled into a 6 mm deep rabbetted channel in the frame. If the species to be kept requires higher humidity or visual separation, transparent or opaque solid plastic panels (0.125 mm thick) can be used instead of the mesh, which might require that a dado slot is cut into the framing

FIG. 1. Front view of cage system including plumbing.

sticks that allows them to be inserted into the slots. The front panels are attached to the other panels with a plastic piano hinge and secured with stainless steel suitcase latches (Fig. 2), while the rest of the panels are fastened with #6 stainless steel woodscrews. These boxes form the upper story of the animals' enclosures. Located below each box is a 35.5 cm x 22.8 cm x 22.8 cm plastic Rubbermaid® container holding a pool of water 5 cm deep. A large plastic sink drain with a 4 mm mesh plastic filter is installed in each container and allows wastewater to be conducted to a floor drain through PVC pipe. An in-line shut-off valve is installed below each sink drain. Below this a PVC tailpiece nests inside the drainage pipe, but isn't directly connected, which allows removal or replacement of the Rubbermaid® containers when necessary.

The screen boxes are secured with #6 stainless steel woodscrews to a 1.86 m x 48 cm x 20 mm thick polyethylene shelf. The Rubbermaid® containers are inserted through four large rectangular openings in the shelf and are supported by the containers' flanges (flared top lips). The support shelf is attached to a wall at the rear, while the front is supported by a 1.82 m long x 5 cm x 5 cm strip of angle aluminum (4 mm thick) and three 30.5 cm x 40 cm x 20 mm thick vertical polyethylene supports.

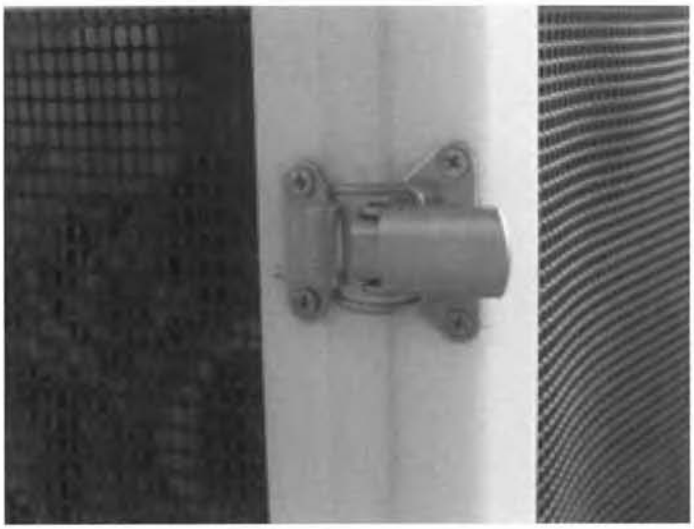

FIG. 2. Stainless steel door latch.

This system can be built for a cost of US $350.00–400.00, if one uses in-house labor. The most expensive component is the polyethylene frame material, which is purchased as a large sheet (1.2 m x 2.46 m) for approximately $150.00–200.00. However, one sheet can be used to build several sets of cages, which can be mounted in rows one above the other, and this significantly lowers the unit cost of each set of cages. Less expensive materials can be substituted for the polyethylene. The benefits of using polyethylene are that it is non-toxic and impervious to water and most chemicals; it maintains stable dimensions (despite fluctuating relative humidity); it is shatterproof and can be cut, drilled and joined under pressure without splintering; and it should give many years of reliable service.

This type of caging system might be suitable for a wide variety of small arboreal or semi-arboreal amphibians. We have used these cages to house adult Canyon Treefrogs (*Hyla arenicolor*), Arizona Treefrogs (*H. eximia*), and Mexican Treefrogs (*Smilisca baudini*). Additionally, we reared recently-metamorphosed frogs of both these *Hyla* species, and the *H. arenicolor* bred in one of the small boxes. The tadpoles were removed and reared through metamorphosis in other cages and returned to these units afterwards.

ZOO VIEW

The first reptile collection at the San Diego Zoo was assembled in 1922 and the first reptile house was the modified International Harvester building, built for the Panama-California Exposition during 1915–16. In 1931, C. B. "Si" Perkins was in charge and lobbied for a better facility; his new building, designed specifically for reptiles, opened on 4 July 1936. This large structure is still home for the collection. Many reptiles are kept outdoors in large enclosures: crocodilians, giant tortoises, and large varanids and iguanids. A series of small buildings named in honor of the late Laurence Klauber, known for his studies on rattlesnakes, house a number of smaller amphibians and reptiles. Klauber was the first curator of reptiles in the 1920s, consulting curator beginning in 1931, and served on the Board of Trustees from 1943 to 1968.

Charles Shaw followed Perkins and developed successful reproductive programs for Galápagos tortoises and other reptiles. When Shaw died, Jerry Staedeli was installed in his post. Later, James Bacon became curator until he died in 1986. Jim was concerned about conservation issues, especially those related to the potential loss of island populations. His assistant, Earl (Tom) Schultz was elevated to his post until he retired several years ago. The present curator, Donal Boyer, was formerly the supervisor at the Dallas Zoo where we were colleagues for over a decade.

Herpetological research at the San Diego Zoo has been ongoing over many years, especially from the Center for Research of Endangered Species (CRES), which began in 1975. Developed to improve captive breeding and health of wild and captive animals, CRES has been in the forefront of zoo conservation initiatives. One of the major thrusts has been the West Indian iguana effort, involving an *in situ* and *ex situ* component. In fact, Allison Alberts, Valentine Lance, John (Andy) Phillips, and retired CRES Director Kurt Benirschke have published many papers on herpetological subjects.

Allison heads the CRES Applied Conservation Division. She has used statistical models based on radiographic measurements to predict oviposition date and clutch size in Cuban iguanas (*Cyclura nubila*) and also studied the effects of incubation temperature and water potential on growth and thermoregulatory behavior. She has predicted gender of lizards

using two dimensional ultrasound imaging and plasma testosterone concentration. Her investigations include seasonal reproductive cycles of the desert tortoise, pheromonal self-recognition in desert iguanas, dominance hierarchies in male lizards, pre-release health screening in animal translocations, chemical and behavioral studies of femoral gland secretions in iguanid lizards, and many other studies on chemical recognition and behavioral aspects of lizards and chelonians. Recently, four Anegada Island iguanas, a species found in the British Virgin Islands, hatched at the CRES off-exhibit reptile research facility. Fewer than 300 individuals remain in the wild and there has been an 80% decline since the 1960s. The Zoo supports a head-starting program on the island and the staff is currently surveying the wild population and investigating nesting ecology. In addition to her work in the Caribbean, Allison has a long-standing interest in the reptiles of southern California, with division staff currently conducting radiotelemetry studies to better understand the behavioral ecology of coast horned lizards, rosy boas, and red diamond rattlesnakes.

When I read her seminal publication "West Indian Iguanas: Status Survey and Conservation Action Plan," which included conservation strategies, taxonomic accounts, action plans, and beautiful color photographs compiled by specialists, it seemed appropriate to ask her to share her accomplishments with our community. Because Allison is so committed to the continued survival of West Indian iguanas, her description of the Cuban iguana program below nicely incorporates her vision of a successful zoo conservation effort using combined expertise and resources for the overall recovery of a species.—*James B. Murphy, Section Editor.*

Ten Years of Conservation Research on Cuban Rock Iguanas

ALLISON C. ALBERTS
Center for Reproduction of Engandered Species
Zoological Society of San Diego, P.O. Box 120551
San Diego, California 92112, USA
e-mail: aalberts@sandiegozoo.org

With funding from the National Science Foundation Conservation and Restoration Biology Program, I and fellow researchers in the CRES Applied Conservation Division began studies of Cuban iguanas on the U.S. Naval Base at Guantanamo Bay, Cuba, in 1992. Our intentions were to gain an understanding of the basic biology of these iguanas, as well as to develop practical conservation strategies for population recovery. For three years, we collected baseline data on population density, social behavior, reproductive hormone cycles, home range size, and daily and seasonal activity patterns. We found a negative relationship between female size and reproductive success, with larger females producing a higher percentage of non-viable eggs. That larger, presumably older, females tend to show greater infertility and egg mortality suggests that reproductive senescence might occur in this long-lived species. We also found that hatchlings from eggs incubated at higher temperatures grow more quickly than those incubated at lower temperatures. Finally, field experiments revealed that temporary alteration of local social structure through translocation of dominant males might represent a valuable management tool for small iguana populations by ensuring that a greater percentage of males have an opportunity to contribute to the gene pool.

As elsewhere in the Caribbean, one of the main threats to iguanas at Guantanamo Bay is a sizeable population of feral cats, which consume large numbers of juveniles each year. In 1995, we released 45 juvenile Cuban iguanas, collected as eggs on the base and reared at the San Diego Zoo, at two locations on the base. These animals were part of a long-term head-starting experiment designed to test whether juveniles that have been raised in captivity until they reach a less vulnerable body size have improved chances for survival against introduced predators in the wild.

Prior to the release, several studies were undertaken with the captive juveniles at the Zoo. Monthly measurements of the distance individual iguanas would allow an observer to approach before fleeing indicated that captivity did not result in a decrease in fear of humans. Food preference tests showed that juveniles were willing to sample unfamiliar native plants after several months on an artificial diet, suggesting that they are unlikely to experience difficulty in adapting to natural food sources. A thorough veterinary screening showed that all of the juvenile iguanas were in good health and could be released safely. A CNN film crew accompanied us to Guantanamo to cover the release, and the story, which aired on both Headline News and Science and Technology Week, generated international attention. Follow-up studies indicated that the released juveniles adapted well to life in the wild. Their growth, thermoregulation, and behavior, particularly with regard to predator avoidance, closely parallel their wild counterparts.

In late 1994 and early 1995, approximately 60,000 Cuban and Haitian migrants arrived unexpectedly on the base. Extensive areas of natural habitat were graded along the coastline to construct temporary housing, resulting in disturbance to natural ecosystems. At the height of the migrant crisis, the dry tropical forest surrounding our study site was reduced to less than 5% of its former extent, and we could only locate a single adult male in the area. With funding from the Zoo, we studied how rapidly and to what degree the iguana population was able to achieve its former dimensions, and how the natural process of recolonization of the area by iguanas correlated with recovery of vegetation at the site. This research provided an ideal opportunity to document the extent to which Caribbean dry tropical forest ecosystems are resilient enough to recover from disturbance, and to study the ecological role that iguanas play in the recovery process.

By 1999, we had documented a relatively stable group of 25 individuals at the site, with approximately 15% turnover in group composition per year. For both males and females, the relationship between body mass and body length was comparable to that of healthy wild iguanas, indicating that iguanas were able to forage

effectively at the site following disturbance. In order to document revegetation of the site, we also measured changes in the biomass of plant material over time. Although the rate of increase slowed in 1999 (1.05 m^3/month) compared to 1998 (1.52 m^3/month), the total biomass of vegetation at the site continued to grow throughout the study period.

Public education is key to the success of any conservation program. Thanks to a supplemental award from the National Science Foundation's Informal Education Program, we have been able to incorporate a public education component into our work on the base. Although Cuban iguanas comprise a conspicuous component of the local fauna and have been adopted as an informal mascot by many base residents, their biology and conservation status are not widely understood or appreciated. A major focus of our educational efforts has been to provide opportunities for the general public to participate actively in our field research effort. On three separate trips in 1997, we offered interested volunteers on the base the opportunity to participate in standardized iguana censusing and help collect data on antipredator and thermoregulatory behavior. Feedback from over 40 participants in the form of surveys was overwhelmingly positive, with 93% of respondents finding the research experience extremely worthwhile, 83% of respondents experiencing a positive shift in attitude regarding scientific research following their field experience, and 90% of respondents indicating that they would recommend the research experience to other base residents.

In collaboration with HVS Productions, we also produced a video that describes the basic biology of iguanas, their conservation status and requirements, and the goals, study methods, and results of our research program. Copies of the videotape have been distributed to the environmental office, library, and schools on the base. On each of our trips to the base, we have offered public lectures at which we provide information on iguanas, their conservation status, and how to appreciate and enjoy them without harming them. We have given numerous presentations to both elementary and secondary students on the base, prepared an endangered species pamphlet for incoming base personnel, and designed an Iguana Crossing sign for sites on the base where road casualties were known to have occurred.

Our work at Guantanamo Bay is but one example of the many contributions zoos are making to the conservation of West Indian iguanas. Over 20 American Zoo and Aquarium Association (AZA) member institutions have provided direct funding and other resources to West Indian iguana conservation projects, primarily in Jamaica, but also in Dominica, the Cayman Islands, the Dominican Republic, the Bahamas, the Turks and Caicos Islands, and the British Virgin Islands. With the help of zoos and other dedicated conservation partners, some of the rarest and most impressive lizards in the world are starting to make a comeback.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 33, Number 1 (March 2002).

GYMNOPHIONA

OSCAECILIA ZWEIFELI (Zweifel's Caecilian). **PREDATION**. Virtually nothing is known about the ecology of *Oscaecilia zweifeli* (Lescure and Marty 2000. Atlas des Amphibiens de Guyane. Patrimoines Naturels, 45). At the field station of Nouragues (4°5'N, 52°41'W 110 m elev.), 8 km N of Saut Pararé, Arataye River, French Guiana, during the rainy season on 25 May 1999, one of us (RB) found, under a rotted trunk on the ground, an *O. zweifeli* (Museúm National d'Histoire Naturelle, Paris [MNHN] 1997.6482) whose head was maintained by the chelicera of an adult giant tarantula, *Theraphosa leblondi* (Theraphosidae) (Fig. 1). The tarantula had produced a silk cocoon around the head of the dead caecilian; the head was already partly digested. When disturbed, the tarantula raised its forelegs and threw urticating setae. This specimen of *O. zweifeli* is the second one known from French Guiana, the species having been recorded in that country only from a single specimen from Cayenne (Lescure and Marty, *op. cit.*).

We thank J.-C. Baloup F. Catzeflis, P Charles-Dominique, M. Dewynter, P. Gaucher, G. Lenglet, and S Lochon for working facilities.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2002 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Theodora Pinou, SSAR Treasurer, Department of Ecology & Evolutionary Biology, Osborn Memorial Labs, Yale University, 165 Prospect Street, New Haven, Connecticut 06520-8106, USA. Fax: (203) 432-5176; e-mail: theodora.pinou@yale.edu

Future Annual Meetings

2002 — Crown Center Hotel, Kansas City, Missouri, USA. 3–8 July (with ASIH, HL)
2003 — Hotel Tropical, Manaus, Brazil (with ASIH, HL)
2004 — University of Oklahoma, Norman, Oklahoma (with ASIH, HL)

About Our Cover: *Brookesia perarmata*

Brookesia is a genus of pygmy chameleons endemic to the island-continent of Madagascar. It is currently comprised of approximately 24 species (Klaver and Boehme 1997. Das Tierreich 109:1–306). At best, this number should be considered tentative as new species are being discovered and others synonymized with known forms.

The largest known species of the genus is the bizarre armored leaf chameleon, *Brookesia perarmata* Angel 1933, reaching a total length of 11 cm (Glaw and Vences 1994. A Fieldguide to the Amphibians and Reptiles of Madagascar, 2nd ed., rev., Verlag GbR, Cologne. 480 pp.). It possesses the largest dorso-lateral spines, arranged in paired longitudinal rows of rosettes, and its body is wider and more heavily built than its congeners. An essentially two-toned coloration, featuring a golden tan head and prominent ear-like ocular cones extending to the rear, contrast sharply with its dark brown body. Lack of a pelvic shield is a further identification point.

The karst limestone ('tsingy') massif of the Bemaraha Plateau, located in west-central Madagascar, is the only known habitat of this species. *B. perarmata* lives on the ground and in low bushes between steep tsingy canyons where it presumably feeds upon a variety of invertebrates.

Virtually nothing can be said of this species' biology in the wild as no field studies have been undertaken in its remote and largely inaccessible habitat. Captive females lay paired eggs which hatch into miniature near-replicas of the adults, but with lighter bodies overall. Captive animals apparently require high humidity levels to thrive, but must not be kept upon wet or even damp substrates.

The cover image of an adult female *Brookesia perarmata* was photographed by **Bill Love / Blue Chameleon Ventures**. He recorded this captive specimen on Fujichrome Velvia (ASA 50) film, using a Nikon F90X camera and SB-21 "ring" flash. Separation and imaging of Love's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

NEWSNOTES

Ermi Zhao Elected to Chinese Academy

Professor Ermi Zhao, senior scientist at the Chengdu Institute of Biology, China's leading center for herpetological research, has been elected to membership in the Chinese Academy of Science. Academician is the highest honor accorded to a scientist in the PRC. Zhao is only the second herpetologist ever elected to the academy, the other being his former teacher, Cheng-chao Liu, author of the classic book, Amphibians of Western China (Chicago, 1950).

Zhao is the author of numerous studies on amphibians and reptiles from all parts of China and has conducted field research throughout the country. He has written eight books, among them two published by SSAR (Studies on Chinese Salamanders, 1988; Herpetology of China, 1993). He has been an active promoter of Chinese herpetological research and conservation and their links to the international community. He served on the Executive Committee of the First World Congress of Herpetology and is active in several international conservation organizations. Ermi Zhao is a longtime member of SSAR and the Society congratulates him on this great honor.

New Herpetological Journal

The Ukrainian Academy of Medical and Biological Sciences has established a new journal, *Gerpetologicheskii Vestnik*. The Editor-in-Chief is Dr. Igor R. Gul of Lvov, Ukraine. This is the first herpetological periodical in Ukraine. It publishes papers on amphibians and reptiles in their natural environment and on keeping and breeding them in captivity, as well as book reviews. Papers are published in Russian, chosen to make the journal more available for a majority of researchers from the ex-Soviet republics. English abstracts are provided, thereby making summaries available to non-Russian speakers. Further information available from: *Dr. Igor R. Gul, P.O. Box 10485, P.O. 49, Lvov 290049 Ukraine.*

Salamandra Now Publishes Articles in English

The quarterly published German herpetological journal *Salamandra* (founded 1965; ISSN 0036-3375), previously a German language only publication, now publishes articles in English. *Salamandra* is one of several journals distributed by the Deutsche Gesellschaft fuer Herpetologie und Terrarienkunde (DGHT). The other DGHT journals such as *amphibia, elaphe, Die Eidechse, Iguana*, and *Radiata* contain German language articles on various aspects of herpetoculture. *elaphe* also publishes articles on ecology and conservation of amphibians and reptiles. *Die Eidechse* involves all aspects of the biology of the family Lacertidae. The turtle and tortoise-centered journal *Radiata* is also published as an English edition. In addition, DGHT publishes the mongraphic se-

ries *Mertensiella*. To this point, 13 volumes on various herpetological subjects have been published completely or partly in English.

Authors are invited to submit English or German language manuscripts with herpetological or herpetocultural content for publication in *Salamandra*. Contributors should follow the instructions for manuscript preparation at:

www.dght.de/salamandra/instructions.htm

For 60 EURO per year one can subscribe to *Salamandra* plus *elaphe* and one of the other DGHT publications of your choice (excluding *Mertensiella*) by surface mail. For details please contact the DGHT office via e-mail: gs@dght.de.

New Bibliography and Index of Herpetological Names, AMNH Novitates

Ernest A. Liner has compiled a bibliography and index to scientific names of amphibians and reptiles, fossil and Recent, published in American Museum Novitates. The Novitates included are all issues from number one through number 3285, published from the years 1921 through 1999.

The bibliography is also set up as a searchable database, thanks to Mark Breedlove. Searches can be made on the basis of author, taxon, title, volume, or year of publication. Both the complete bibliography/index and the searchable database are available on the web at the following address, then click on "Publications":

http://research.amnh.org/herpetology

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one-page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due on 15 October 2002, with notification by 1 December 2002. Grantees are expected to complete their Academy visit by 15 September 2003. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

The CAS holdings are included in the Department of Herpetology database:

http://research.calacademy.org/herpetology/catalog/

Brett Stearns Award for Chelonian Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round-trip transportation and limited per diem expenses—to researchers who wish to visit our collections to support their work in chelonian biology. Preference will be given to graduate students.

Proposals should include a short, one-page description of the research project and a budget. In the case of graduate students, a letter of support from the student's faculty advisor is required.

Proposals are due on 15 October 2002; notification will be made by 1 December 2002. Awardees are expected to complete their Academy visit by 15 September 2003. Please call (415) 750-7039 for further information.

Proposals should be sent to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

The CAS chelonian holdings are included in the Department of Herpetology database:

http://research.calacademy.org/herpetology/catalog/

New AMNH Website

The Center for Biodiversity and Conservation at the American Museum of Natural History is pleased to announce the launch of its new website: http://research.amnh.org/biodiversity/. Of particular interest to herpetologists is the site's ongoing report of recent herpetofaunal surveys of Vietnam (listed under Biotic Surveys):

http://research.amnh.org/biodiversity/vietnamresearch/

For comments or inquiries regarding the website or the CBC's herpetological program in general, contact Raoul Bain (e-mail: bain@amnh.org).

An Invitation from the Editor of *BioScience*

BioScience, ranked 5/51 journals in the Biology category of ISI's Journal Citation Report, is the preeminent journal for overviews of research in the biological sciences, with strong suits in organismal and environmental biology and ecology. In addition to research overviews we also publish essays in a variety of areas pertinent to Biology and its practice. With a paid circulation of about 8,500 copies per month, we reach an extremely broad readership, ranging from advanced high school students and teachers to professional biologists and policymakers.

The member organizations of the American Institute of Biological Sciences represent a largely untapped source of authors, who may not always be aware of *BioScience*'s broad reach and unique audience. Instructions for manuscript preparation may be found at our website:

http://www.aibs.org/bioscienceguide/resources/contributors.html

Additional information may be obtained from the Editor, Matthew H. Greenstone, Ph.D., Science Editor, *BioScience*, 2404 Northwood Lane, Edmond, Oklahoma 73013, USA; e-mail: mgreenstone@aibs.org.

Journal of Kansas Herpetology

The Kansas Herpetological Society is pleased to announce the premier issue of the *Journal of Kansas Herpetology*. Initiated with issue Number 1 in March 2002, the *Journal of Kansas Herpetology* replaces the former publication of the Society, the *Kansas Herpetological Society Newsletter*. The content of this new scientific periodical will consist of more scholarly works, which will undergo a professional peer review process. The new journal will continue to publish all Society business items, as well as the annual KHS Amphibian, Turtle, and Reptile Counts. Additional information available from: Travis W. Taggart, KHS Editor (e-mail: ttaggart@fhsu.edu).

New Website: *Early Classics in Biogeography, Distribution, and Diversity Studies: To 1950*

This service consists of a bibliography "enhanced" in several ways, including the addition of links to Web-based biographical information on the authors involved, and the full-text (as collected in several ways) of many of the entries. It is meant to serve advanced students and faculty involved in related studies and course work.

The goal of this project is to identify and make electronically available, as possible, those primary sources (especially periodical articles) that have most affected the evolution of our thoughts on the geographical and ecological distribution and diversity of life. The target field is biogeography; not only does this study have a long and distinguished history extending back to before the advent of the theory of natural selection, but it is also highly interdisciplinary, incorporating elements of many other sciences—including ecology, paleobiology, geology, conservation studies, physical geography, evolutionary biology, bioclimatology, and systematics—into its own emphasis on "what lives where, and why." This site may be accessed at:

<http://www.wku.edu/~smithch/biogeog/>

MEETINGS

Meetings Calendar

18–21 July 2002—26th Annual Meeting of the International Herpetological Symposium, Sheraton Westport Hotel Plaza, St. Louis, Missouri, USA. Information: www.kingsnake.com/ihs/26meeting.html.

25–28 November 2002—VII National Meeting, Sociedad Herpetológica Mexicana (SHM) (Mexican Herpetological Society), Universidad de Guanajuato, México. Information: www.iztacala.unam.mx/shm/.

OBITUARIES

© 2002 by Society for the Study of Amphibians and Reptiles

Dean E. Metter 1932–2001

ROBERT POWELL
Department of Biology, Avila College
Kansas City, Missouri 64145-1698, USA
e-mail: powellr@mail.avila.edu

Dean E. Metter died on 23 June 2001 at the age of 68. His life and professional work focused on Missouri, where he was a member of the Zoology faculty at the University of Missouri-Columbia for 30 years. "Doc," as he was universally known to his students until his retirement in 1994 (after which he began signing his frequent correspondence "ex-Doc"), began life in Champaign, Illinois, married Sylvia Michlig in 1954 in Sheffield, Illinois, earned a bachelor's degree from Eastern Illinois University, a master's degree from Washington State University, and a doctorate from the University of Idaho in 1963. He began his zoological career interested primarily in fishes, and, to his dying day, ranked the lowly bluegill as nature's greatest wonder (although in later years, I suspect it was almost exclusively due to its outstanding gustatory qualities). While in the Pacific Northwest, he became enamored with amphibians, and they subsequently became his life-long passion. He joined the faculty at Missouri in 1964, and began a long tenure of introducing students to his favorite animals, the habitats in which they lived, and the natural processes to which they were subjected.

An excellent, albeit demanding teacher, Doc was feared by several generations of pre-medical students, some of whom actually survived his comparative anatomy course (many of those later came to appreciate his efforts when they found gross anatomy manageable). However, Doc's greatest impact as an instructor was on the students who passed through his zoology, herpetology, and evolution courses. Many of us were not only challenged to do better than we thought possible, we became sufficiently excited about the subject matter that we pursued higher degrees and, in several instances, became educators in our own right. Doc was a living example of the precept that any educator's best tool is his own enthusiasm for the subject.

That enthusiasm was not immediately evident to the student who merely showed up to class and was subjected to a non-stop 50 minutes of information delivered clearly and logically, but very,

very rapidly. However, the student who made the effort to stop by before or, more usually, after class (Doc was a morning person and generally scheduled his courses during the earliest time slot permitted by the University), was rewarded with Doc's undivided attention and a willingness to address concerns, provide additional information, or sometimes just chat — assuming, of course, that the student's motive wasn't limited to queries regarding what would be covered on the next exam. Doc had a notable lack of patience with "learners" who learned only to pass an exam.

In contrast, Doc provided many opportunities for the student who became motivated to pursue the learning process beyond the classroom. Unlike many of my herpetological colleagues, I didn't hunt snakes at a tender age, instead my interest in herps was triggered by Doc's herpetology class, in which I had enrolled only to fulfill a requirement. Once in, however, I became enthralled, especially with the lizards. Because I was having some difficulty with the characters that distinguish the skinks, I asked if I could come in outside of class time and look them over. Doc not only let me into the lab, but stayed close to make sure that I would benefit from my uncharacteristic burst of diligence.

Doc was a big believer in putting classroom learning to the test in the field. He regularly scheduled trips on which all of the current students were invited. Initially amazed that so many former students and graduate students participated, we soon learned why. Doc expected the same effort in the field that he did in the classroom (and that extended to chores around camp as well as collecting animals). He had learned (maybe the hard way?) that hungry students didn't perform very well. Consequently, the meals were noted for both quality and quantity; I can remember many a feast during which I ate pounds of salad, several potatoes, and two thick steaks. Additional motivation to consume heartily was provided by the fact that any left-overs inevitably appeared in the next morning's eggs. Costs were kept reasonable because we did all of our own cooking, camped only where it was free, and, although he never admitted it in so many words, Doc covered any budget overrun out of his own pocket.

Doc mentored numerous master's students and three Ph.D. students. The total would have been higher, but Doc saw too many graduates having to settle for jobs well below their abilities or outside their specialties to feel good about contributing to the glut of applicants for all-too-few jobs. As a result, he took doctoral students only when they had positions in hand and, even then, only after a harrowing interview during which he spelled out in excruciating detail the realities of work in academia. Although I was subjected to the standard protocol, Doc had, years before, taken the sting from his presentation. On an exceptionally hot day in the Ozarks, when the critters were showing more sense than we were by not being out and about, we finally gave up. Sitting chest-deep in Table Rock Lake waiting for cooler evening hours, Doc noted that "it's a good life when you're paid to do what you like doing."

Doc was a naturalist of the old school, interested in everything, and he never stopped learning or being a teacher. When he took anyone on long drives through central Missouri, during which he'd repeatedly visit a number of favorite places, he'd never cease pointing out the vast diversity of the flora, even to those who had tagged along on many a previous occasion. In Stewart Hall, where Doc resided for most of his years at MU, he established and maintained an extensive collection of live animals. Although all of his students, to varying degrees, learned about and often helped care for the current set of residents (and frequently made the trek to the animal lab to collect mice and rats for what became regularly scheduled and well-attended events), it was when casual passers-by or groups of school children came through, that another side of Doc came to light. Never talking down to anyone, he conveyed many of the fundamental ideas that define biology to kids for whom a visit to the "snake room" was the highlight of the school year.

Doc read widely and never confined his own ongoing education to biological topics. He was amazingly well-informed (and quite opinionated) about almost everything. Wandering through the state, he had acquired quite a collection of arrowheads. During a brief visit to drop off some information related to my dissertation, he noticed that my daughter, then 11 years old, seemed fascinated by his display of artifacts. Ignoring me, he spent nearly an hour explaining how the Indians had made the various pieces, the uses for which they were designed, and the sources of the rocks they had used. She was spellbound. Although she had never before shown any interest in history or anthropology, she spoke of that day for many years.

Doc did excellent research, but published fewer than 35 papers. However, his dissertation work on *Ascaphus truei*, the tailed frog of the Pacific Northwest, is still considered a definitive work on the species. He attended few meetings (although he encouraged his students to do so). Doc's contention was that the good papers would show up in journals within a few months, and the others weren't worth the bother. What he did do was encourage his students to tackle tough problems and to use methods that would not only help find the answers, but would translate into marketable skills. He was always available to his students, whether sitting in on a study session before comps or helping in the field. I'll never forget the late February day we were seining for spotted salamanders (*Ambystoma maculatum*) in an upland Ozark pond. Never one to dump on students any chore he wasn't willing to take on himself, Doc found himself on the far end of the seine in water suddenly deeper than his waders were high. Moving faster than any human had a right to move, he ploughed through the water and up the bank, flopped on his belly facing down the hill, and gave a huge sigh of relief as the 33° water flowed back into the pond. Few professors would risk such an experience for a mere grad student. Along the same lines, Doc saved me many a trip to Columbia by walking over to the graduate school to enroll me for another semester. When I finally completed my dissertation, the entire grad school staff commented on how fortunate I was to associate with the only prof who would make the effort to save a student some time and a little money.

Doc obviously had a kind heart, but he didn't often let it show. The phrase I heard more than once at his memorial service was "compassionate ass-chewing" — and many of us had been on the receiving end of one, often more than once. We never resented these occasions. For one thing, they were always one-on-one, never public, and, secondly, we invariably deserved it. Interestingly enough, being chewed out by Doc was considered a tribute of sorts. He never bothered with folks he felt were incapable of improvement, so his attention served as an affirmation of sorts. Doc rarely complimented anyone face-to-face, but frequently bragged about them behind their backs. He felt free to criticize

any of us, but would not abide us or anyone else bad-mouthing his students and friends behind their backs (however, if the target was present and able to defend itself, it was open season).

Though not adverse to picking up a phone, Doc relied on long, informative letters, handwritten on yellow legal pads, to maintain long-distance relationships. His letters were beautifully written and filled with insights and humor. Doc also taught many of us how to write effectively. More than once, he returned papers to me on which he had bled profusely, often making pointed comments on my incomparable ability to string thoughts together in such a way that convoluted sentences became entire paragraphs. When I was named an editor of a professional publication, he bemoaned the desperate state of herpetology (but was secretly pleased, I think, that I had learned at least a little of what he had tried to teach me).

Doc was a co-founder of the Bobby Witcher Society, the bi-annual meetings of which were an excuse to see old friends and eat mounds of bluegill filets (summer) or various unusual repasts that relied heavily on the warped imaginations of members and their ability to provide strange fare for the table (winter). The real legacy of the Society, however, was the scholarship fund that grew well beyond the founders' fondest hopes, largely due to Doc's diligent oversight. The interest from the fund served as a means of rewarding outstanding herpetology students who intended to continue their education and make a career in some aspect of vertebrate biology. The Society recently agreed to fund an SSAR Grant-in-Herpetology to support field-based student research. The formal announcement of the aptly named Dean E. Metter Memorial Award will occur in 2002.

Doc touched many people, his family, his friends, his colleagues, his students (many of whom became life-long friends), the recipients of Witcher Awards, and even the visitors to the snake room in Stewart Hall — and every one of us was better for it.

Acknowledgments.—I thank Richard Daniel, Kathleen Metter, and the members of the Bobby Witcher Society for sharing recollections and comments.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **Omar Torres-Carvajal**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can now be found at: http://www.herplit.com/contents.

Systematics of Microteiid Lizards

The neotropical family Gymnophthalmidae is composed of 178 species included in 36 genera, which occur from southern Mexico to Argentina, in the Caribbean, and on some islands of the continental shelves of South and Central America. The authors used a total of 2379 bp of mitochondrial and nuclear sequences of 50 species to perform phylogenetic analyses under the optimality criteria of maximum parsimony and maximum likelihood. Confidence in resulting nodes was assessed by bootstrap and partitioned Bremer support analyses. Three species of macroteiid lizards, *Cnemidophorus ocellifer*, *Kentropyx calcarata*, and *Tupinambis quadrilineatus*, were used as outgroups. Based on the topology recovered by maximum parsimony, the authors proposed several taxonomic changes. The family Gymnophthalmidae was divided into four subfamilies, two of which are new, and a new tribe within Gymnophthalminae also was proposed. Additionally, the authors commented on the evolution of fossoriality and ecological implications of the phylogenetic relationships of microteiid lizards.

Reproductive Biology of an African Colubrid

The brown house snake (*Lamprophis fuliginosus*) is a widespread African colubrid that readily breeds in captivity. Previous work on the reproductive biology of this species has used information from single females, or females from various localities—both approaches failed to account for geographic variation in clutch size and offspring size. The author reports data for 13 animals collected in Arusha, Tanzania. Snakes were fed approximately 10% of their body mass in mice per week, and maintained in individual cages under a 14:10 light/dark cycle at 28°C. Females were paired with a male at least once a week. Clutch size (5–8) and clutch mass were weakly correlated with female SVL. There was about 20% variation among females in egg mass, but little variation in individual clutches. Egg mass was not correlated to clutch size. Because clutch size can be influenced by food intake, clutch size of captive snakes may not accurately represent what occurs in the wild. However, egg masses in snakes from specific localities may be affected local selection pressures.

Snake Behavior and Phylogenetic Correlation

Male-male fighting (MMF) in snakes is restricted to males during the breeding season, and the presence or absence of this behavior has taxonomic trends. The authors had two main goals for this study: 1) to assess the origin, sequence, and frequency of MMF in higher-level snake taxa; and 2) to address the apparent correlation between MMF with mode of prey subjugation. The latter notion was tested with concentrated-changes tests and the subtree decomposition method. Currently, MMF is not documented for 9 of 26 higher-level snake lineages, which led the authors to use the

heuristic method for scoring MMF. Snake phylogenies were slightly modified from studies, and MacClade was used to reconstruct the character evolution of MMF. Several most-parsimonious reconstructions of MMF were obtained, and all trees indicated that MMF ahs been indepentdently gained and lost a minimum of 4–8 times during the evolution of snakes. Results indicate there is some evidence for a significant correlation between MMF and constriction and/or envenomization as the primary mode of prey subjugation. The authors explain this correlation as independent responses to ecological limitations imposed by diet.

Snake-Induced Fear in Human Behavior

Humans can detect threatening events regardless of focused and conscious attention. According to the primary author's fear model, threats are evaluated and then receive preferential access to arousal systems for further processing. The authors tested whether fear-relevant stimuli (e.g., images of snakes and spiders) could be processed at an automatic level, including the efficient selection of the stimuli from complex visual displays. Mean reaction time of participants was shorter for fear-relevant than fear-irrelevant images. Participants who were fearful of snakes or spiders had faster reaction times than participants who were not fearful. These results suggest that humans have a predisposition to preferentially detect attention toward threatening stimuli such as snakes and spiders.

Female Mimicry in Male Garter Snakes

Males of several unrelated animal species might mimic females in order to steal inseminations from rivals or avoid aggression. The authors report on some male garter snakes (*Thamnophis sirtalis parietalis*) that can secrete female-like phermones and attract other males. It is suggested that these "she-males" benefit by reduced predation and temperature increases from the resulting balls of amorous males. The phenomenon is restricted to the first two days of emergence from hibernation. Empirical data confirmed that emerging females warmed up faster if they were covered by courting males. Further experiments indicated that she-males tended to attract males if they had a cooler temperature—warmer she-males did not secrete as many pheromones as colder she-males.

Diving Behavior of Marine Green Turtles

Marine turtles are excellent model organisms for studying long-distance animal migration. Several species move thousands of kilometers between feeding areas and breeding grounds. The authors studied diving behavior of several female *Chelonia mydas* that nest on Ascension Island and migrate to feeding grounds along the Brazilian coast. Satellite transmitters were attached to 12 individuals at the end of the nesting season on Ascension Island. In addition, time/depth recorders were attached to five turtles that had been displaced 60 and 270 km away from the island. In general, there was a tendency for the submergence duration to be short and significantly longer at night than during the day. However, periods of longer submergences were registered during migration. Short dives (2–4 min) were associated with turtles diving near the surface (<5 m), whereas long dives (20–30 min) were associated with turtles diving deeper (5–20 m). Apparently, the key factor driving swimming depth in green turtles is minimization of their cost of transport. Swimming below the surface where drag is reduced could be the optimum strategy. In addition, by diving below the surface, green turtles reduce the extent to which they are silhouetted against the surface, thereby becoming less susceptible to predators, such as sharks.

Immune Function and Fitness of Side-Blotched Lizards *Uta stansburiana*

Density-dependent competition affects species fitness. Immunosuppression has been suggested as one of the mechanisms having a deleterious effect on fitness at high population densities. The authors used a Californian population of *Uta stansburiana* to analyze the effects of female morphotype and number of neighbors on immune function and survival during two reproductive seasons. This dense population is characterized by females exhibiting two heritable throat-color morphs—orange and yellow. Mark-recapture methods were used to investigate survival of females and hatchlings. Immune function was assessed by measuring immune response of individual lizards to tetanus toxoid. Standard ELISA with a modified laboratory protocol was used. Breeding females of both throat-color morphs that were surrounded by many neighbors had suppressed immune function, with stronger effects in orange females. Evidence for genetic correlation between female morphotype and immune responsiveness was found by comparing the immune responsiveness between daughters of orange and yellow females. These results indicate that fitness of side-

blotched lizards is jointly influenced by female morphotype and density-dependent immune function. The authors are interested in investigating more correlations between throat color of *Uta stansburiana* and other fitness-related factors, such as clutch size and egg mass.

Vocalization and Parental Care of *Tribolonotus gracilis*

Most species of lizards that are known to vocalize belong to the families Gekkonidae or Pygopodidae. In these taxa, vocalizations generally fall into two categories—advertisement or distress. The authors studied vocalization of the crocodile skink, *Tribolonotus gracilis*, and its implications in parental care. One pair of adult crocodile skinks was used to record defensive vocalizations, whereas three pairs were used in parental care observations. Male calls had a longer duration and faster pulse rate than female calls. Calls of both sexes contained harmonics and shared a similar overall frequency range. Parental care was exhibited mainly by females, which were always found curled around their eggs. Females exhibited defensive open-mouth lunges whenever eggs were handled by the observer. This defensive display included vocalizations in about half of the trials. In addition, neonates were observed to stay close to their mothers for two weeks after hatching. The authors propose that vocalization of crocodile skinks plays a defensive role, which may be associated with parental care. Also, they suggest that the acoustic sexual differences might be caused by sexual dimorphism within the larynx or trachea.

Chameleon Speciation: Oceanic Dispersal or Continental Break-up?

Chameleons are thought to have biogeographic patterns that are congruent with the Gondwanan break-up of Africa and Madagascar 165 myr ago. The authors tested the Gondwanan vicariance hypothesis by constructing area cladograms based on phylogenetic analyses of 52 species of chameleons. Molecular, morphological, and behavioral data were included in the parsimony-based analysis. The results supported the monophyly of Chamaeleoninae. The most basal clades were represented by *Brookesia*, which is endemic to Madagascar. Thus, the resulting area cladogram showed that the most basal clades occur in Madagascar, whereas more derived lineages are distributed in Madagascar, Africa, the Seychelles, and India. This area cladogram is inconsistent with proposed Gondwanan break-up vicariance models. Instead, it supports a post-Gondwanan origin of chameleons in Madagascar, with subsequent oceanic dispersal to Africa, India, and the Seychelles. Other evidence consistent with this post-Gondwanan origin model includes presence of chameleons in isolated volcanic islands, fossil record of the group, and molecular clock mtDNA divergences. The species radiation of chameleons is similar to species radiations of other animals that have been demonstrated to have post-Gondwanan origins in Africa or Asia with subsequent transmarine migrations.

Factors Affecting Foraging Behavior of the Red-Backed Salamander, *Plethodon cinereus*

Terrestrial salamanders of the genus *Plethodon* are among the animals that show defensive responses to a variety of chemical cues, such as damaged tissues of conspecifics or chemicals released by predators. In *Plethodon*, the responses include avoidance of substrates, change of activity levels, or delay of emergence from refugia. The authors investigated costs of responses of red-backed salamanders *Plethodon cinereus* to chemical cues of eastern garter snakes *Thamnophis sirtalis*. One snake and 48 salamanders were collected in New York. Foraging activity of salamanders exposed to snake-soiled water and salamanders exposed to unsoiled water was measured. This was achieved by measuring the number of actions oriented toward a prey (cricket) per minute. Salamanders exposed to snake-soiled water had lower foraging activity than those exposed to unsoiled water. In addition, the authors found that foraging activity of individuals in both odor treatments showed a bimodal periodicity consistent with natural activity patterns that are controlled by internal biorhythms. Food deprivation or sex did not appear to affect salamander foraging activity and responsiveness to chemical cues. Consideration of behavioral biorhythms in this kind of study is suggested by the authors.

Foot Muscles of Myobatrachids

There are many hypotheses and no agreement regarding the taxonomy and phylogenetic relationships among members of Myobatrachidae. Subfamilies Myobatrachinae and Limnodynastinae are widely supported. In an attempt to find informative phylogenetic characters, the author described the foot musculature of *Limnodynastes tasmaniensis* and used that description as a basis of comparison for other myobatrachid frogs. Given

that many myobatrachids are burrowing frogs, the author also studied the relationship between foot musculature and burrowing. All 21 genera of Myobatrachidae and several representatives of Hylidae, Pelobatidae, and Pelodytidae were examined. Variation within Myobatrachidae was found in 25 muscles. In some cases, there was considerable intraspecific and intrageneric variation (e.g., M.m. transversi metacarporum I-IV). The extent of the insertion of the m. abductor brevis plantae digiti V was the only character that consistently separated Myobatrachinae from Limnodynastinae. Other clades were supported by several apparent synapomorphies. A new muscle, m. adductor praehallucis, apparently associated with the fossorial habit, was described. Additionally, differences in the musculature associated with the metatarsal tubercles were found among several clades. According to the author, these differences indicate that burrowing evolved several times in Myobatrachidae.

Environmental Contaminant Accumulation and Effects on Snakes

Reptiles are crucial to the proper functioning of many ecological processes and should therefore be included in any ecological risk assessment. World Conservation Union's 1996 Red List of Threatened Animals includes 67 species of snakes, of which 15 are listed as critical. Because snakes reside in middle and higher trophic levels, they are susceptible to the bioaccumulation of environmental contaminants. The authors summarized the available information on bioaccumulation and effects of organic and inorganic contaminants and radionuclides/radiation on snakes. They found information on organic contaminants (e.g., DDT, aldrin, endrin, mirex, oxychlordane) for Colubridae, Boidae, Viperidae, and Elapidae. Data on inorganic contaminants (e.g., cobalt, copper, zinc, boron) was available for the same families, as well as for Typhlopidae, Leptotyphlopidae, Aniliidae, Xenopeltidae, and Acrochordidae. In contrast, information on radionuclides/radiation was found for Viperidae and Colubridae only. Given that this information is poor (no data for six families), the authors conclude that more ecotoxicological studies on snakes are badly needed. Some studies presented in this article indicate that snakes are ideal bioindicators. Finally, Campbell and Campbell suggest that representative species of reptiles should be included in the U.S. Environmental Protection Agency or any other regulatory agency's list of species used in pesticide testing.

From Lizards to Snakes

Radical transformations in body plan of animals are often associated with the origin of higher taxa. The authors studied the evolution of body form of anguid lizards to analyze the transition from lizardlike to snakelike body form. Morphological, ecological, and molecular data of 23 species were analyzed with statistical phylogenetic methods. Regarding the evolutionary changes in body form, the authors found that the evolution of limb-reduced and elongate body form occurred independently in three different clades—anniellines, *Ophiodes*, and anguines. The data suggested that there is not necessarily a sequence of evolutionary change from body elongation to limb reduction to digit reduction. Hypothesized relationships between limb reduction and digit reduction, and limb reduction and body elongation were supported by multivariate and bivariate analyses. No consistent relationship was found between miniaturization and the evolution of elongate body form, limb reduction, or digit loss. The hypothesized relationship between limb loss and burrowing was not supported by Maddison's concentrated-changes test. Similarly, the presence of a pectoral girdle in some elongate, limbless forms does not support the idea that elongation and loss of the forelimbs are simply the result of anterior expansion of more posterior domains of Hox gene expression. Finally, given that the data suggested a slow transition from lizard to snakelike body form, the authors support the idea that the origin of higher taxa may proceed gradually through the same processes that occur within groups and among closely related species.

Systematics and Conservation of Chinese Turtles

Demand of Chinese markets is one of the primary causes for the decimation of Asian turtle populations. Over the past 16 years, 13 new geoemydid turtles have been described from China. Unfortunately, most of these recent descriptions are based on type specimens purchased through the Hong Kong animal trade, which has caused problems, such as simultaneous description of the same species by separate authors. Furthermore, failure to collect more specimens at the alleged type localities has led several authors to suggest either falsification of some localities or that these new species represent intergeneric hybrids. The authors investigated the phylogenetic affinities and provenance of two recently described species—*Mauremys iversoni* and *Cuora serrata*— using 22 specimens representing 10 species acquired from animal trade and museum collections. Allozyme variation was studied as the first test of phylogenetic affinity. In addition, phylogenetic analyses were performed to infer the evolutionary relationships of mtDNA lineages using maximum parsimony and maximum likelihood. Both allozyme and mtDNA data provided evidence that all the specimens of *M. iversoni* and *C. serrata* included in the analyses resulted from multiple, recent hybridization events. Given

that there is no evidence that *M. iversoni* and *C. serrata* are valid species, and given the propensity of distantly related turtles to hybridize, the authors propose to reconsider the systematic status of the specimens examined. They conclude that investigating the origin and validity of new species of turtles described from pet trade specimens is critical for conservation efforts.

Observations on Hibernacula and Overwintering Ecology of Eastern Hog-nosed Snakes (*Heterodon platirhinos*)

MICHAEL V. PLUMMER
Department of Biology, Box 12251, Harding University, Searcy, Arkansas 72149, USA
e-mail: plummer@harding.edu

Hibernacula and overwintering ecology of the hognose snake *Heterodon platirhinos* are known only from anecdotal observations and may differ in some respects from that of many snakes (Anderson 1965; Platt 1969). In addition, because overwintering ecology of reptiles may vary geographically (Gregory 1982; Sexton et al. 1992), it is important to study it in various parts of a species' range. In the course of monitoring *H. platirhinos* by radiotelemetry for a study of spatial ecology and survivorship during the activity season (Plummer and Mills 2000), I made observations on individual snakes over the winter months in the south central part of the species' range. These observations contribute to our understanding of the hibernacula and overwintering ecology of this species.

Temperature-sensitive transmitters (Telonics CHP-2P; <5% of snake mass) were implanted into adult *H. platirhinos* following the procedures of Reinert (1992). One male was monitored over winter in 1992, and two females and four males were monitored over winter in 1993. A minimum-maximum thermometer recorded shaded air temperatures 1 m above ground. The study area (N35°16', W91°43') is located in the easternmost part of the Arkansas River Valley subdivision of the Ouachita Mountain region of Arkansas, USA (Foti 1974). Topography is rolling to hilly and varies from approximately 60 m to 120 m above sea level. The sandy soils are thin and often rocky. The occasionally stunted vegetation of the xeric higher areas is upland deciduous woodland whereas that of the more mesic lower areas is upland deciduous forest (Foti et al. 1994). Common trees included oaks, *Quercus stellata* and *Q. marilandica*, hickory, *Carya texana*, and juniper, *Juniperus virginiana*. Natural grassy openings were common, especially in the higher areas. Other grassy openings included roads, trails, abandoned fencerows, pipeline and powerline right-of-ways, pastures, and mowed fields. Burrows of the mole, *Scalopus aquaticus*, were common throughout most of the study area.

The normal activity season for *H. platirhinos* at this locality is mid-April to mid-October during which inactive snakes seek refuge under the cover of grass or surface litter. Snakes typically do not use mole burrows during the activity season (Plummer and Mills 2000). During short periods of cold weather just before and after hibernation (i.e., November and March), *Heterodon* also took refuge under the cover of grass or surface litter. Snakes temporary retreated into mole burrows only occasionally occurred during this time. At this locality, winters are mild and continuous hibernation usually occurred from about December through February. By tracking telemetered snakes, I located individual *H. platirhinos* in 13 different hibernacula from December through February. Snakes were located at irregular intervals (1–4 times per week) in the mid to late afternoon. Transmitters functioned well and without problems at the lower than activity season temperatures.

All *Heterodon* hibernated singly in one or more mole burrows. The hibernacula were distributed throughout the approximate 250 ha study area in open woodlands (N = 8), a fencerow at the edge of a grassy field (N = 3), and a grassy pipeline right-of-way (N = 2). Two snakes changed hibernacula in December–February. One female moved 14 m on 29 December to a new hibernaculum and 24 m on 2 February and 22 m on 6 February to new hibernacula. One male moved 56 m on 7 February to a new hibernaculum. Each hibernaculum shift was preceeded by a period of one or more sunny days when maximum air temperatures ranged from 14 to 21°C.

One male abruptly moved in each of two years from a distant portion of its home range to hibernacula on a power line right-of-way. This snake traversed the same path each year, moving a minimum of 800 m in 3 d (1993) and 700 m in 2 d (1994). Dates of arrival at the hibernacula were 6 October 1993 and 7 October 1994. The two hibernacula were located within 150 m of each other. There were no obvious habitat differences between the location left and the hibernacula sites (both were open woodland habitat with distinct habitat edges). Although movement to and from hibernacula and hibernating singly at this latitude have been reported in other snake species (Gregory 1982; Sexton et al. 1992), migration and fidelity to a distant hibernaculum in snakes most often is associated with communal hibernacula at high latitudes (Gregory 1984).

I excavated one hibernaculum on 22 January 1994 and found the snake in a small chamber located approximately 75 cm from the mouth of the burrow at a depth of 25 cm. The soil temperature of the chamber was 4.5°C (measured with a thermocouple probe) and the body temperature of the snake was 4.7°C (measured with the temperature-sensitive transmitter). In December–February, body temperatures of snakes in their hibernacula averaged 10.1 ± 2.4°C (SD) (range 4.7–13.6°C, N = 16) in 1992 and 11.4 ± 1.3°C (9.8–14.6°C, N = 23) in 1993. These relatively high temperatures were within the normal range of body temperatures for hibernating reptiles (1–15°C; Gregory 1982) and support the notion that hibernating snakes often seek the warmer parts of their hibernaculum (Sexton et al. 1992). During this same period, snakes occasionally basked when maximum air temperatures exceeded ap-

proximately 18°C for several consecutive days. Body temperatures of basking snakes in December–February averaged 23.7 ± 3.7°C (21.1–26.3°C, N = 2) in 1992 and 23.1 ± 6.1°C (16.6–32.6°C, N = 6) in 1993.

One male was found dead on 5 December 1993 near the mouth of its hibernaculum where it had been monitored since 17 November. The snake was last observed basking in the same position and location on 28 November. Freezing was the likely cause of death as minimum air temperatures had dropped to at least –6°C during that time and there was no gross physical damage to the body or evidence of disease.

Percent change in the body mass of hibernating snakes determined from measurements taken at highly variable times before and after the December–February hibernation averaged 0.3 ± 9.3% (–11.3% to 11.4%, N = 5). Based on the intensity of monitoring and the times of body mass measurement, body mass change due to overwintering probably was best represented by one female who weighed 244 g on 15 October and 238 g on 2 February. The 2.5% loss in mass during this time was associated with a mean body temperature of 11.4 ± 1.3°C (N = 23), two hibernacula shifts, and at least four bouts of basking in December–February. It is unknown whether the mass loss represented lean mass, lipid, or water loss.

My observations differ from various anecdotal reports on hibernation in *H. platirhinos* because they report histories of individual snakes monitored over extended times. The mole burrow hibernacula described herein as well as various other kinds of hibernacula have been reported previously for *H. platirhinos* (Anderson 1965; Arndt 1980; Neill 1948; Platt 1969). In contrast to opportunistic encounters which limit the discovery of hibernacula to only where one searches (e.g., Neill 1948), telemetric observations should better represent unbiased overwintering "preferences" because, assuming no transmitter effect, they demonstrate choices of hibernacula made by individual snakes (Weatherhead and Charland 1985). Consistent with these results are reports that *Heterodon* usually are absent in hibernacula harboring other snake species (Platt 1969). For example, in Missouri, *Heterodon* are absent in the limestone edge hibernacula used by most other snakes, choosing instead to hibernate in mammal burrows in nearby open fields (Anderson 1965). It is known that *Heterodon* may dig their own hibernacula (Arndt 1980; Platt 1969). The loose, sandy soils on my study area appeared to be suitable for burrowing and I have observed *Heterodon* to dig when foraging (unpubl.). The lack of burrowing for hibernacula at this locality may have resulted from the high availability of natural mole burrows.

Acknowledgments.—I thank M. May and N. Mills for assistance in the field, J. Hollaway and S. Henson for permitting me access to properties under their charge, Harding University for providing support, and O. Sexton and S. Plummer for comments on the manuscript.

and

JAMES R. McCRANIE
10770 Southwest 164th Street
Miami, Florida 33157-2933, USA

The years that have transpired since we last updated the Honduran herpetofauna (Wilson and McCranie 1994a) have been productive ones, resulting in major additions to our knowledge. Unlike two previous lists (Wilson 1983; Wilson and McCranie 1994a), we treat here only the reptile component of the herpetofauna, inasmuch as the amphibians will be dealt with in McCranie and Wilson (2002). That book treats 116 species of amphibians, including two caecilians, 25 salamanders, and 89 anurans. These figures compare with a total of 89 species, including 3 caecilians (see McCranie and Wilson 2002, for an explanation of the decrease of one species), 17 salamanders, and 69 anurans in the 1994 list.

As with the 1983 and 1994 lists, additions to the reptile fauna have occurred through range extensions or taxa being described as new to science. In addition, a few taxa have been resurrected or added to the reptile fauna as a result of the clarification of the status of some Honduran populations. Currently, the total number of species of Honduran reptiles is 217, up from 188 on the 1994 list, a 15.4% increase. The increase of 29 taxa involved numerous modifications, as detailed below. No changes occurred in the list of crocodilians. Fourteen species of turtles are currently recog-

nized on the Honduran mainland and in Honduran waters. This figure is two fewer than that in the 1994 list, inasmuch as *Dermatemys mawii* has been deleted from the list, as no material from Honduras has made its way into collections (McCranie and Wilson, in prep.), and *Chelonia agassizi* is no longer recognized as a species distinct from *C. mydas* (Kamezaki and Matsui 1995; Karl and Bowen 1999; Parham and Zug 1996). The lizard fauna increased from 69 to 88 species, due to descriptions of 11 new species (as well as one taxon listed in 1994 as *Celestus* sp. and two species of *Ctenosaura* named as new based on separating Honduran populations from those in the remainder of two taxa indicated in the 1994 list) and eight range extensions. The snake fauna now comprises 113 species, up from 101 in the 1994 list. The change in number results from the description of five new species (as well as one taxon listed in 1994 as *Ninia* sp.), six range extensions, and one resurrection. Since the 1994 list, then, 16 descriptions of new species have appeared in print or are in press. In addition, the range of 14 species has been extended into Honduras.

As with the previous paper (Wilson and McCranie 1994a), the reptilian species are listed alphabetically under each order. In addition, each name is followed by a parenthetically-enclosed number referring to a numbered reference in the Literature Cited section in which that species was reported as occurring in Honduras.

TESTUDINES (14 species)

Caretta caretta (11)
Chelonia mydas (11)
Chelydra serpentina (45)
Dermochelys coriacea (11)
Eretmochelys imbricata (11)
Kinosternon leucostomum (45)
Kinosternon scorpioides (45)
Lepidochelys olivacea (11)
Rhinoclemmys annulata (45)
Rhinoclemmys areolata (6; also see reference 48)
Rhinoclemmys funerea (45)
Rhinoclemmys pulcherrima (45)
Staurotypus triporcatus (45)
Trachemys scripta (45, as *Chrysemys ornata*)

CROCODILIA (2 species)

Caiman crocodilus (45)
Crocodylus acutus (45)

SAURIA (88 species)

Abronia montecristoi (37)
Abronia salvadorensis (59, as *Abronia montecristoi*; see reference 3)
Ameiva ameiva (50)
Ameiva festiva (45)
Ameiva undulata (45)
Anolis allisoni (45)
Aristelliger georgeensis (1)
Aristelliger praesignis (50)
Basiliscus plumifrons (45)
Basiliscus vittatus (45)
Celestus bivittatus (59)
Celestus montanus (45)
Celestus scansorius (35)
Cnemidophorus deppii (45)
Cnemidophorus lemniscatus (45)
Cnemidophorus motaguae (45)
Coleonyx mitratus (45)
Corytophanes cristatus (45)
Corytophanes hernandesii (26)
Corytophanes percarinatus (36)
Ctenosaura bakeri (45, as *Enyaliosaurus bakeri* [in part]; see reference 5)
Ctenosaura flavidorsalis (17)
Ctenosaura melanosterna (2)
Ctenosaura oedirhina (5)
Ctenosaura similis (45)
Eumeces managuae (4)
Eumeces sumichrasti (45)
Gonatodes albogularis (45)
Gymnophthalmus speciosus (45)
Hemidactylus brookii (16)
Hemidactylus frenatus (7)
Hemidactylus mabouia (38)
Iguana iguana (45)
Laemanctus longipes (45, [in part])
Laemanctus serratus (23)
Leiocephalus carinatus (50)
Lepidophyma flavimaculatum (45)
Mabuya unimarginata (45, as *Mabuya mabouya*)
Mesaspis moreletii (45, as *Barisia moreleti*)
Norops amplisquamosus (43)
Norops bicaorum (15)
Norops biporcatus (45, as *Anolis biporcatus*)
Norops capito (45, as *Anolis capito*)
Norops crassulus (45, as *Anolis crassulus*)
Norops cupreus (45, as *Anolis cupreus*)
Norops cusuco (30)
Norops heteropholidotus (18)
Norops humilis (45, as *Anolis humilis*)
Norops johnmeyeri (54, as *Anolis johnmeyeri*)
Norops kreutzi (30)
Norops laeviventris (45, as *Anolis laeviventris*)
Norops lemurinus (45, as *Anolis lemurinus* [in part])
Norops limifrons (45, as *Anolis limifrons* [in part]; see reference 56)
Norops lionotus (24, as *Norops oxylophus*)
Norops loveridgei (45, as *Anolis loveridgei*)
Norops muralla (20)
Norops ocelloscapularis (21)
Norops pentaprion (45, as *Anolis pentaprion*)
Norops petersii (32)
Norops pijolensis (44, as *Norops pijolense*)
Norops purpurgularis (25)
Norops roatanensis (19)
Norops rodriguezii (56)
Norops rubribarbaris (20)
Norops sagrai (45, as *Anolis sagrei*)
Norops sericeus (45, as *Anolis sericeus*)
Norops sminthus (45, as *Anolis sminthus* [in part])
Norops tropidonotus (45, as *Anolis tropidonotus*)

Norops uniformis (56)
Norops utilensis (14)
Norops wampuensis (29)
Norops yoroensis (31)
Norops zeus (19)
Phyllodactylus palmeus (45)
Phyllodactylus tuberculosus (45)
Polychrus gutturosus (45)
Sceloporus malachiticus (45)
Sceloporus squamosus (45)
Sceloporus variabilis (45)
Sphaerodactylus dunni (45)
Sphaerodactylus glaucus (8)
Sphaerodactylus millepunctatus (45, as *Sphaerodactylus continentalis*)
Sphaerodactylus notatus (50)
Sphaerodactylus rosaurae (45)
Sphenomorphus assatus (28)
Sphenomorphus cherriei (45, as *Scincella cherriei* (in part])
Sphenomorphus incertus (56)
Thecadactylus rapicauda (45)

SERPENTES (113 species)

Adelphicos quadrivirgatus (60)
Agkistrodon bilineatus (60)
Alsophis cantherigerus (50)
Amastridium veliferum (60)
Atropoides nummifer (60, as *Bothrops nummifera*)
Boa constrictor (60)
Bothriechis bicolor (60, as *Bothrops bicolor*)
Bothriechis marchi (60, as *Bothrops marchi*)
Bothriechis schlegelii (60, as *Bothrops schlegeli*)
Bothrops asper (60, as *Bothrops atrox*)
Cerrophidion godmani (60, as *Bothrops godmani*)
Chironius grandisquamis (60)
Clelia clelia (60)
Coniophanes bipunctatus (60)
Coniophanes fissidens (60)
Coniophanes imperialis (60)
Coniophanes piceivittis (60)
Conophis lineatus (60)
Corallus annulatus (9)
Crisantophis nevermanni (60)
Crotalus durissus (60)
Dendrophidion nuchale (60, as *Dendrophidion clarki*)
Dendrophidion percarinatum (60)
Dipsas bicolor (60)
Dryadophis dorsalis (60)
Dryadophis melanolomus (60)
Drymarchon corais (60)
Drymobius cloroticus (60)
Drymobius margaritiferus (60)
Drymobius melanotropis (60)
Elaphe flavirufa (60)
Enulius bifoveatus (27)
Enulius flavitorques (60, [in part])
Enulius roatanensis (27)
Erythrolamprus mimus (60)
Ficimia publia (60)
Geophis damiani (58)
Geophis fulvoguttatus (33)
Geophis hoffmanni (60)
Hydromorphus concolor (60)
Imantodes cenchoa (60)
Imantodes gemmistratus (60)
Imantodes inornatus (60)
Lampropeltis triangulum (60)
Leptodeira annulata (60)
Leptodeira nigrofasciata (60)
Leptodeira septentrionalis (60)
Leptodrymus pulcherrimus (60)
Leptophis ahaetulla (60)
Leptophis mexicanus (60)
Leptophis modestus (60)
Leptophis nebulosus (60)
Leptotyphlops goudotii (60)
Loxocemus bicolor (60)
Masticophis mentovarius (60)
Micrurus alleni (24)
Micrurus browni (33)
Micrurus diastema (60)
Micrurus nigrocinctus (60)
Micrurus ruatanus (60)
Ninia diademata (60)
Ninia espinali (34)
Ninia maculata (42)
Ninia sebae (60)
Nothopsis rugosus (46)
Omoadiphas aurula (22)
Oxybelis aeneus (60)
Oxybelis brevirostris (60)
Oxybelis fulgidus (60, [in part])
Oxybelis wilsoni (51)
Oxyrhopus petola (60)
Pelamis platurus (60)
Pliocercus elapoides (60; see reference 49, as *Urotheca elapoides*)
Porthidium nasutum (60, as *Bothrops nasuta*)
Porthidium ophryomegas (60, as *Bothrops ophryomegas*)
Pseustes poecilonotus (60)
Rhadinaea godmani (60)
Rhadinaea kinkelini (60)
Rhadinaea lachrymans (39)
Rhadinaea montecristi (60)
Rhadinaea tolpanorum (10)
Rhinobothryum bovallii (60)
Scaphiodontophis annulatus (60)
Scolecophis atrocinctus (60)
Senticolis triaspis (60, as *Elaphe triaspis*)
Sibon anthracops (60)
Sibon carri (60)
Sibon dimidiatus (60)
Sibon longifrenis (42)
Sibon nebulatus (60)
Spilotes pullatus (60)
Stenorrhina degenhardtii (60)
Stenorrhina freminvillii (60)

Storeria dekayi (60)
Tantilla impensa (57)
Tantilla lempira (60)
Tantilla melanocephala (60)
Tantilla schistosa (60)
Tantilla taeniata (60, [in part])
Tantilla tritaeniata (57)
Tantillita lintoni (60)
Thamnophis fulvus (60)
Thamnophis marcianus (60)
Thamnophis proximus (60)
Tretanorhinus nigroluteus (60)
Trimorphodon biscutatus (60)
Tropidodipsas fischeri (60, as *Sibon fischeri*)
Tropidodipsas sartorii (60, as *Sibon sartorii*)
Typhlops costaricensis (53)
Typhlops stadelmani (60, as *Typhlops tenuis*; see reference 40)
Ungaliophis continentalis (60)
Urotheca guentheri (42)
Xenodon rabdocephalus (60)

On 5 August 1998 at 1530 h, ALC noticed an extraordinary aggregation of adult copperheads *(Agkistrodon contortrix).* She was following a well-used hiking trail in Clinton State Park near the city of Lawrence in Douglas Co., Kansas, USA. The snakes lay in resting coils on both sides of the trail, 0.6–3 m from its edge, among loose rocks of a limestone outcrop. Seven snakes were closely associated in a group, touching one another or separated by less than 5 cm; there were four in another such group 1 m away; and a twelfth snake was located about 1.5 m from its nearest neighbor. The sky was overcast after light rain and the temperature was 24°C. After 5 min, seven of the snakes took refuge in three holes that were 0.1–0.3 m apart. At 1810 h, when ALC rechecked the site just after two bicyclists had passed on the trail, four snakes remained—three in shade and one in sunshine.

At 1500 h on 6 August, ALC and HSF returned and captured all snakes that could be found—10 from the site discovered on 5 August, and 4 from a site about 100 m farther west on the same outcrop. On 9 August, ALC returned at 1140 h and caught two more at the site of the large aggregation, and at 1500 h she caught one more 2 m away. On 10 August at 0945 h she returned again and caught three more copperheads at the same site, while a fourth escaped. Except for one adult male, all these snakes proved to be gravid females. Thus, the large aggregation contained at least 17 snakes (15 gravid females, 1 male, and 1 individual that escaped), and four gravid females were found (and captured) in the smaller group. These snakes subsequently produced their litters in captivity. On 6 and 12 September, females and neonates were returned to the park and released at sites well removed from the trails and other places of concentrated human activity.

Allen (1868) first documented aggregating behavior of gravid female copperheads, citing A. C. Bennett, who had killed female copperheads found in several different groups in Massachusetts—five on 5 July, seven later in July, and six in September. In Connecticut, Finneran (1948, 1953) found five groups of female copperheads (4, 4, 5, 7, and 9) on a wooded hilltop in 1941, 1942, 1946, and 1947. Minton (1944) reported associations of pairs and threes in Indiana, and Fitch (1960) recorded associations of two, three, and four in Kansas. Over a 50-yr period (1948–1998) at The University of Kansas Natural History Reservation, HSF captured 335 gravid females in mid–late summer (July, August, and early September), of which 275 (82%) were found singly (many

in traps) and 55 others were in associations of two to five (mean ± SE = 2.39 ± 0.84).

Our observations, as well as literature accounts (e.g., Finneran 1953), indicate that when gravid females are found together, they are associated with a "den" (hole in the ground, rock crevice, hollow log) into which they can escape from predators or unfavorably low or high temperatures. They are also in areas exposed to sun for part of the day, permitting them to bask. These associations apparently stem from mutual affinity because the snakes might be gathered tightly although nearby locations that appear to be equally suitable are unoccupied (Fitch 1999). Mutual security might lead females to associate because a predator attacking one of them would be at risk of bites from others lying within striking range. Furthermore, the association between parturient females and neonates, and that between neonates of the same or different litters, might confer some benefit in mutual security.

The association of 16 gravid females with the prospect of about 100 neonates in an area of perhaps 0.0065 ha would reduce each snake's opportunity to feed. A female could stay with her litter for several days and the neonates may remain at the birthing site even longer. Although females take little or no food during late pregnancy, and thus would not compete for food during this time, they are somewhat emaciated after the birth of their litters, and are ready to take prey. The neonates shed their skins when they are about a week old; by then they are using up their store of abdominal egg yolk and are ready for their first meal. There is usually little overlap between adults and neonates in sizes of prey animals taken and in kinds of prey (Fitch 1960, 1999), but barring rapid and long-distance dispersal, intense competition seems inevitable within each age class at such high density.

This unusually large aggregation could have resulted from a high population density in a habitat with few optimal brooding sites. Exploration of the rock outcrop revealed other sites with exposed rock, but these did not seem to receive as much sun during the day as the site occupied (ALC observation). That this locality could sustain a dense snake population is given support by comparing these females with those from two other populations located in areas that differ in food abundance. The average length and embryo count of the females from Clinton Lake were 635.8 ± 11.2 mm SVL and 6.65 ± 0.24 embryos, respectively. These values are intermediate but on the high side in comparison with females from two other locations: The University of Kansas Biotic Succession Area, a seemingly ideal habitat with a high population of prey *(Microtus ochrogaster)*, and The Natural History Reservation, an area of dense forest where prey is much less available (Fitch 1999). The average length and embryo count of 15 gravid females taken from the succession area between 1986 and 1997 were 644.8 ± 8.3 mm SVL and 7.13 ± 1.15 embryos. In comparison, a 40-yr sample (1958–1998) of Reservation snakes had an average SVL of 606.5 ± 4.8 mm and contained 5.37 ± 0.17 embryos. Although no effort was made to estimate copperhead population density at the Clinton Lake site, population density is correlated with size and fecundity of females, probably through the joint causal factor of food availability (Fitch 1999).

We cannot state conclusively why these snakes formed such a large aggregation. It is unprecedented in the literature and, in light of our current knowledge of the biology of these snakes, could have social or environmental causes.

Reports of amphibians utilizing the burrows of other vertebrates are common. Several species of amphibians are found in gopher tortoise burrows (Lips 1991), and ambystomatid salamanders are often observed in association with small mammal burrows (Douglas and Monroe 1981; Gordon 1968; Hamilton 1946; Loredo et al. 1996). We report the use of black-tailed prairie dog (*Cynomys ludovicianus*) burrows by a population of tiger salamanders (*Ambystoma tigrinum*) at a prairie dog town at Wind Cave National Park (WICA) in southwestern South Dakota. We also provide some evidence for commensalism and suggest future studies to determine if this type of relationship exists between these salamanders and prairie dogs.

During a herpetological survey of WICA in 1996, we observed several tiger salamanders at a prairie dog town at Bison Flats, WICA (Fig. 1). The prairie dog town at Bison Flats surrounds a temporary pond used in 1996–1998 by breeding tiger salamanders (Fig. 2). Based on these observations we designed a sampling protocol to determine 1) the number of burrows used by salamanders, 2) the total number of salamanders using burrows, and 3) the pattern of salamander activity in burrows through the spring and summer. In 1998, we also wanted to determine if salamanders used specific burrows continually through the summer and determine the spatial extent of salamanders in burrows in relation to the pond. For comparison, we also visited the Pringle prairie dog town (WICA) and the Custer prairie dog town at Custer State Park (CSP) in 1996 and 1997 (Fig. 1). In 1998, we focused only on the Bison Flats prairie dog town and expanded the area of our survey to determine if the 1996–1997 surveys were missing occupied burrows farther from the pond.

During the spring and summer 1996–1998, we conducted a total of 17 surveys of prairie dog towns (Table 1). Surveys were conducted between 2045–2400 h and varied in duration from 19–156 minutes. Night air temperatures to the nearest 0.5°C were taken within the prairie dog town at the beginning of each survey using a hand-held thermometer one meter above the ground. During night surveys at each prairie dog town, we systematically checked from 100–187 (five surveys, mean = 161.6) burrows in 1996, 90–113 (five surveys, mean = 106.4) burrows in 1997, and 117–491 (seven surveys, mean = 264.4) burrows in 1998. We shined a light into the entrance of each burrow, and recorded whether tiger salamanders were present. Because the surveys were conducted at night, it is possible that we missed burrows or checked the same burrow twice. When salamanders were found in a burrow, the light caused them to retreat quickly into the burrow and out of view. Therefore, if a burrow was checked a second time, a false unoccupied burrow would be recorded. Although we do not believe that this occurred often, it would serve to underestimate the number of burrows occupied. Bison Flats prairie dog town became the focus of this study after we noticed high levels of salamander activity at this prairie dog town during studies of the adjacent pond.

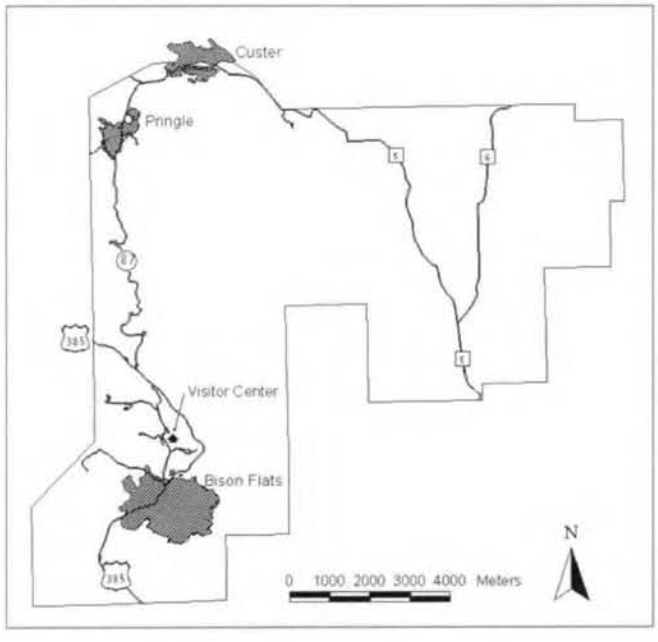

FIG. 1. Map of Wind Cave National Park indicating the location of the Bison Flats, Pringle, and Custer prairie dog towns surveyed in 1996–1998.

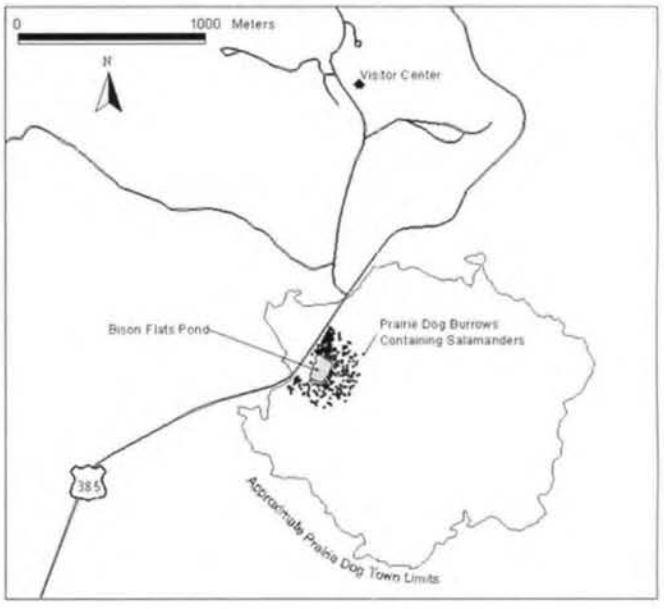

FIG. 2. Map of the Bison Flats prairie dog town showing the location of the pond, burrows occupied by salamanders in 1998, and the approximate extent of the prairie dog town limits.

We compared the number of burrows occupied and percentage of burrows occupied per survey with the date, temperature at the start of each survey, and the number of days since the last rain using linear regression (SAS Institute Inc. 1997). Percentages were arcsine transformed prior to analyses. Date was used to determine if the pattern of burrow occupancy changed during the spring and summer. Temperature and number of days since the last rain were used because salamander activity could be associated with these environmental variables. Because of the intentional increase in the number of burrows checked at Bison Flats in 1998, that is, an average of greater than 100 more burrows were checked in 1998 than the previous years, percentages of burrows occupied are lower for 1998. Therefore, we present analyses of both the number of burrows occupied and percentage of burrows occupied at Bison Flats from 1996–1998. Finally, we used ANOVA to determine if the number of burrows occupied was different among the three years.

In 1998, we marked burrows that were occupied by salamanders with a stake for future identification and measured the distance from the center of the pond to each of these burrows. To evaluate the spatial extent of burrow use, we used a chi-square test to determine if the number of occupied burrows in each 30 m-wide concentric ring around the pond was different (Sokal and Rohlf 1995). The expected number of occupied burrows was calculated based on the area of each successively larger concentric ring (i.e., 30–60 m, 60–90 m, 90–120 m, and 120–150 m) divided by the total area. The 0–30 m area was not included because the pond inundated it. The zero point was defined as the deepest point of the pond. We also monitored marked burrows in subsequent surveys to determine if salamanders used the same burrows.

Night air temperatures during surveys ranged from 15–25°C

(Table 1). Tiger salamanders were found in few burrows at the Pringle prairie dog town in 1996–1997 and in no burrows at the Custer prairie dog town in 1996 (Table 1). For May–July of all three years, 22–54 prairie dog burrows were occupied by salamanders at Bison Flats, clearly many more than at the Custer or Pringle prairie dog towns (Table 1). In 1996 and 1998, there were drops in occupancy of varying magnitudes in August (Fig. 3), a month when the ephemeral pond at Bison Flats usually tended to dry. However, burrow occupancy by salamanders remained consistent through early August in 1997. The number of burrows occupied was negatively correlated with date for the three years combined ($r = -0.73$, $P = 0.003$, N = 14) as was the percentage of burrows occupied ($r = -0.75$, $P = 0.002$, N = 14). A similar negative relationship was detected for each year separately with a significant result for the number of burrows occupied in 1998 ($r = -0.77$, $P = 0.04$, N = 7), but not in 1996 ($r = -0.97$, $P = 0.15$, N = 3) or 1997 ($r = -0.80$, $P = 0.20$, N = 4). There was also a negative relationship between percentage of burrows occupied and date with a significant relationship in 1997 ($r = -0.90$, $P = 0.05$, N = 4), but not in 1996 ($r = -0.95$, $P = 0.20$, N = 3) or 1998 ($r = -0.52$, $P = 0.23$, N = 7). Non-significant results in 1996 and 1997 were likely because of small sample sizes as both correlations were strong. Overall, burrow occupancy by tiger salamanders decreased through the course of the spring and summer (Fig. 3). There was no relationship between the number of burrows occupied and the temperature at the start of each survey ($P = 0.26$, N = 12) nor with the percentage of burrows occupied and temperature ($P = 0.98$, N = 12). Furthermore, there was no relationship between the number of burrows occupied and the number of days since the last rain ($P = 0.44$, N = 14) nor with the percentage of burrows occupied ($P = 0.29$, N = 14). There was no difference among years in the number of burrows occupied ($F_{2,11} = 0.15$, $P = 0.86$).

More occupied burrows than expected were found in the 60–90 m and 90–120 m areas, less burrows than expected in the 120–150 m area, and the same number as expected in the 30–60 m area ($\chi^2 = 56.46$, df = 3, $P < 0.0001$). We marked 86 occupied burrows from 11 July to 13 August 1998. Of these marked burrows, 72 were checked in subsequent surveys and 38.9% had at least one salamander present. Thus, repeated use of the same burrows existed to some degree at Bison Flats.

Our data show the spatial extent and temporal pattern of black-tailed prairie dog burrow use by tiger salamanders during the spring and summer. The pond at the center of the Bison Flats prairie dog town may explain the higher percentage of burrow occupancy compared with Pringle and Custer prairie dog towns. At Bison Flats, salamander burrow occupancy was consistent in May–August 1997 when the pond still held some water, but in 1996 and 1998 burrow occupancy dropped when the pond dried during August of each year (Fig. 3). Even though burrow occupancy numbers were low in September 1998, salamanders were still present (Table 1; Fig. 3). Additionally, an anecdotal observation on 3 October 1998 found three salamanders in burrows (D. Frankfort, WICA, pers. comm.). The negative relationship between burrow occupancy and date could represent either decreasing activity levels or migration out of the area. We do not know whether tiger salamanders were still present, but inactive, at the prairie dog town after our surveys concluded.

We cannot discern whether the drop in the number of salamanders observed in 1996 and 1998 was because of decreased activity or migration from the study area. Post-breeding dispersal distances have been reported for other species of ambystomatid salamanders. California tiger salamanders (*Ambystoma californiense*) leaving breeding ponds traveled a mean distance of 35.9 m (range = 8–129 m) and settled in ground squirrel burrows

83% of the time (Loredo et al. 1996). Two studies of post-breeding dispersal in *Ambystoma maculatum* documented mean dispersal distances of 192 m (range = 157–249 m) (Kleeberger and Werner 1983) and 150 m (range = 6–220 m) (Douglas and Monroe 1981). Migration out of the study area is unlikely because of the distance from this area to other suitable habitat (i.e., ~1.5 km to the nearest wooded cover and ~1.75 km to the nearest permanent water). Radio-tracking of a subset of individuals is needed to determine if salamanders hibernate in prairie dog burrows or if they migrate out of the area.

Almost 40% of burrows marked and subsequently rechecked had salamanders present. Though we did not mark individuals, use of the same burrow during more than one survey indicates repeated or continual use by one or more salamanders and suggests the salamanders might be residents for at least the spring and summer. However, mark and recapture studies are needed to determine if salamanders occupy one or more burrows over the course of the summer. The expansion of sampling efforts in 1998 resulted in checking nearly twice the number of burrows, yet the number of burrows occupied did not increase (Table 1). This relationship is reflected in the analysis that showed there were more occupied burrows than expected between 60–120 m and less occupied burrows than expected beyond 120 m. Salamander activity might be restricted to close proximity to the pond.

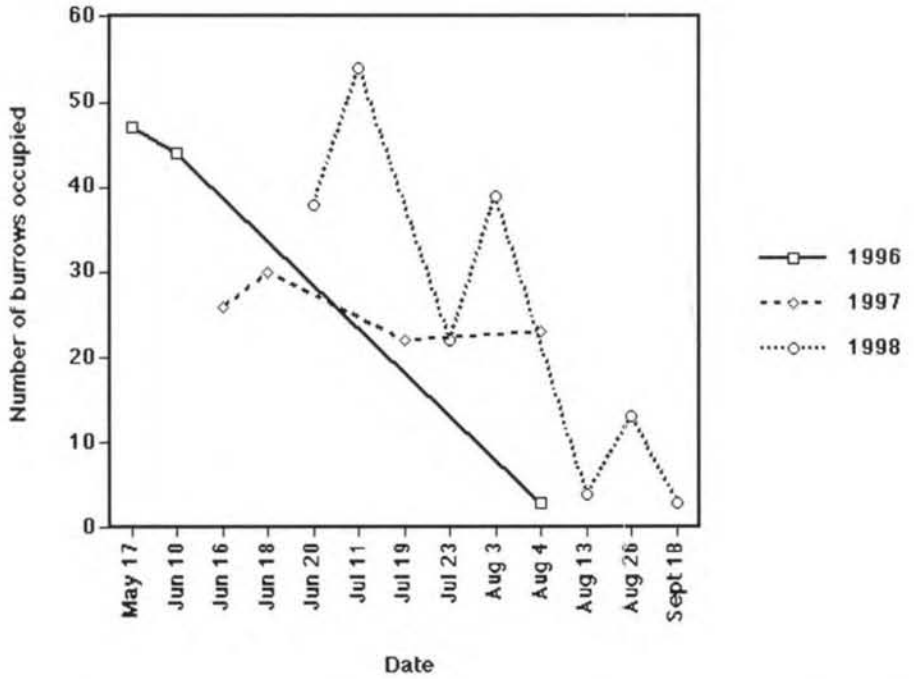

FIG. 3. Number of burrows occupied by date for surveys conducted at the Bison Flats prairie dog town in 1996–1998.

The potential benefits for tiger salamanders living in prairie dog burrows at Bison Flats include an abundance of burrows to use as shelters or hibernation sites, proximity of water for breeding, and a potential source of invertebrate prey attracted to prairie dog feces. Black-tailed prairie dog burrows are remarkably stable environments, with winter temperatures ranging from 5–10°C, summer temperatures from 15–25°C, and a relative humidity that is generally higher within burrows than on the surface (Hoogland 1995). Hoogland (1995) recorded an average relative humidity of 88% in burrows. The benefits of such stable temperatures and humidity levels are important in habitats such as the prairies of western South Dakota, where summers can be hot and dry and winters extremely cold. In summer, access to burrows would allow salamanders to remain underground during the day and become active above ground at night. This potentially decreases the risk of predation and desiccation for tiger salamanders. The use of prairie dog burrows for hibernacula would also offer advantages, such as relatively high and constant temperatures and humidity. Additionally, prairie dogs have anti-predator behaviors, such as mobbing potential predators and plugging holes (Hoogland 1995), which might benefit tiger salamanders.

Lips (1991) suggested that gopher tortoise feces retained within the burrow chamber might attract insects and subsequently insect-feeding amphibians. We observed both fecal pellets and insects around the entrances of prairie dog burrows. Salamanders might forage in close proximity to burrows, where insect abundance might be higher and there is shelter nearby. Future studies comparing the characteristics of burrows occupied by salamanders versus unoccupied burrows might provide important information concerning salamander requirements.

We have documented the spatial extent and temporal pattern of tiger salamander burrow use in a black-tailed prairie dog town over three years. These observations provide a starting point for investigations into a commensal relationship benefiting salamanders at Bison Flats prairie dog town. Additionally, observations of multiple salamanders per burrow (Table 1), often stacked on top of one another, raise interesting questions concerning previously documented territorial behavior in ambystomatid salamanders that warrant further study (Ducey 1989; Ducey and Ritsema 1988; but see Martin et al. 1986). This tiger salamander aggregation at Bison Flats presents an opportunity to study intraspecific and interspecific interactions of *A. tigrinum* in the field.

Acknowledgments.—Funding from the Northern Prairie Wildlife Research Center, U.S. Geological Survey, Biological Resources Division, was instrumental in completing this research. Encouragement by D. Johnson and D. Larson of this research center is gratefully acknowledged. We could not have completed this work without the assistance of D. Kenney and D. Roddy of WICA, who supported this work during the field seasons and provided occasional accommodations. We thank E. Delany for providing the maps used in Figures 1 and 2 and B. Muenchau for providing WICA precipitation data. D. Cardace and K. Ruff were instrumental in organizing and conducting surveys in 1998. Surveys were completed with the help of R. S. Ferguson, E. Taylor, S. Cleaves, H. Walls, G. Greer, J. Wilcox, S. Billig, P. Hundleg, B. Oen, S. Dukti, C. Harlan, P. Orosz, D. Frankfort, and G. Goodrich. F. Janzen, P. Ducey, D. Granfors, D. Johnson, J. Jundt, S. Marks, and two anonymous reviewers commented on this manuscript and made many helpful suggestions.

Little is known about diseases affecting wild populations of box turtles (*Terrapene* spp.). To our knowledge, there are only three published reports. Evans (1983) diagnosed two *T. carolina* with chronic bacterial pneumonia. Both individuals died after exhibiting signs of emaciation, discharge of a cream-colored exudate from the nares, and marked respiratory distress characterized by open-mouth breathing. A mixture of gram-negative bacteria, including *Morganella morgani*, *Acinetobacter calcoaceticus*, *Serratia marcescens*, and *Pseudomonas* sp. was isolated from both turtles. The collective mixture was considered the etiological agent of the pneumonia. Schwartz et al. (1984) reported ear infections in some individuals of a population of *T. ornata*. The etiology of the infections was undetermined. Tangredi and Evans (1997) documented 19 *T. carolina* from scattered locations on Long Island, New York, with one or more of the following signs: listlessness, ocular and nasal discharge, conjunctivitis, swollen eyelids, and inflammation of the middle ear. No single etiologic agent was identified from either microbiologic or histopathologic investigations. The authors speculated, however, that the pathogenesis of the infections might have resulted from low-level exposure to organochlorines.

Recently, *Mycoplasma agassizii* was isolated from a wild *T. c. bauri* with upper respiratory tract disease (URTD) in Florida (M. Brown, pers. comm.). *M. agassizii* is known to cause URTD in wild desert tortoises (*Gopherus agassizii*, Brown et al. 1994) and gopher tortoises (*G. polyphemus*, Smith et al. 1998). Upper respiratory tract disease is contagious and may be a major source of mortality in many tortoise populations (Berry 1997). Clinical signs of URTD include intermittent serous, mucoid, or purulent nasal discharge, ocular discharge, conjunctivitis, swollen eyelids, eyes recessed into the orbits, and dull skin and scutes (Brown et al. 1994; Jacobson et al. 1991).

From May 1997 to October 2000, a population of *T. c. carolina* was monitored using radio telemetry in a southern Appalachian wetland. During the study period, high mortality occurred in this population, apparently as a result of an infectious disease. In this paper we report the general characteristics of the disease, necropsy results from two individuals that died, and blood tests that detect exposure to *Mycoplasma* sp.

The study area is a 95-ha floodplain of Tulula Creek in Graham Co., North Carolina, USA (elev. 785–800 m). A complete description of the site is in Rossell et al. (1999). Each year a maximum of ten turtles with carapace lengths > 10 cm (measured using calipers) were radio-tagged with 15 g transmitters (Wildlife Materials, Inc.). Transmitters were mounted on the rear edge of the carapace with galvanized wire and never exceeded 7% of the mass of any turtle.

Sex and age of turtles were recorded when possible, using eye color and plastron shape (Schwartz et al. 1984; Stuart and Miller 1987). Age was estimated by the mean number of growth rings on four randomly selected carapace scutes (Ewing 1939). All turtles were permanently marked by notching marginal scutes (Cagle 1939).

Turtles (N = 34) were located at least weekly from mid-May through mid-August and biweekly from mid-August until they entered their hibernacula. Twenty-two turtles (64%) were monitored ≤ 1 yr, eight turtles (24%) were monitored 1–2 yr, and four turtles (12%) were monitored 2–3 yr. Because turtles did not start dying from disease until mid-September 1997, individuals were not regularly examined for signs of disease until 1998. Transmitters were removed from six animals with no signs of disease during the study because they moved long distances outside the study area. Transmitters were placed on new individuals as they were encountered in the field.

Of the 34 *T. c. carolina* (20 M, 12 F, 2 unknown) that were radio-tagged, seven (21%) died while being monitored. Five turtles (2 M, 2 F, 1 unknown) died in 1997, one male died in 1998, and one male died in 2000. Turtles that died in 1997 and 1998 all exhibited clear ocular and nasal discharge, and swollen eyelids prior

to death. Clear ocular and nasal discharge also were observed in ca. 50% (N = 14) of turtles that did not die during 1997 and 1998. These signs generally manifested during the summer and disappeared within 1–4 weeks after the initial observation prior to hibernation. The turtle that died in 2000 exhibited labored breathing, coughing, and discharge of a large amount of yellowish exudate. This turtle also appeared listless and moved very little 1–2 d prior to death.

In 1997 and 1998, one recently deceased *T. carolina* was taken each year to the Western Disease Diagnostic Laboratory in Arden, North Carolina, for necropsy. Necropsies included preserving major organs in 10% buffered formalin, examining tissues histologically for signs of disease, and culturing aerobic bacteria from lungs, kidneys, spleens, intestines, and subcutaneous abscesses.

Gross examination of turtle 1, a 20-year old female, revealed a 1.5 cm nodule containing laminated caseous exudate on the side of the neck. The lungs, trachea, and upper respiratory tract all were unremarkable, as were the circulatory, urinary, and reproductive systems. The stomach and most of the intestine were empty. Histological examination of this turtle revealed multiple foci of necrosis in the liver, spleen, and lungs that were associated with thrombosis of small arterioles in each of the organs. Scant inflammatory cells (primarily heterophils) associated with the thrombi also were observed. Bacterial cultures recovered *Enterobacter* sp. and *Proteus* sp. from a subcutaneous abscess, the lungs, and kidneys. *Proteus* sp. also were recovered from the intestines.

Gross examination of turtle 2, a 30-year old male, revealed bluish colored eyes and small ulcerated areas on the skin near the base of the neck. The lungs were mottled, and hemorrhage and necrosis of the oropharyngeal mucosa, as well as foci of hemorrhage along the intestinal mucosa and serosa were evident. Histological examination revealed multiple foci of acute hemorrhagic necrosis and abundant bacterial clusters in the heart, lungs, liver, kidneys, intestines, and spleen. Bacterial cultures recovered *Pseudomonas* sp. from the lungs and kidneys, *Proteus* sp. from the oropharynx, and *Proteus* sp., *Citrobacter* sp., and *Serratia* sp. from the intestines.

In August 1999, blood samples were taken from radio-tagged turtles to determine whether they had been exposed to *Mycoplasma* spp. Approximately 0.25–1.00 ml of blood was collected from seven turtles without any known clinical signs of disease. Samples were drawn and processed for plasma serology following procedures by Raphael and Jacobson (1997). Plasma samples were sent to the Mycoplasma Research Laboratory in Gainesville, Florida, where they were tested for the presence of antibodies to *M. agassizii* using enzyme-linked immunosorbent assay (ELISA) tests (Schumacher et al. 1993). This test has been validated only for *Gopherus agassizii* and *G. polyphemus*. However, ELISA tests are indicative of exposure to *Mycoplasma* sp. in *T. carolina* (M. Brown, Univ. of Florida, pers. comm.). Test results are expressed as ratios between the optical density of a sample and that of a negative control. Samples with ratios > 3 are considered seropositive, ratios > 2 and ≤ 3 are considered suspect, and ratios ≤ 2 are considered seronegative.

Results of ELISA tests indicated that three turtles were seropositive (ratios: 3.84, 5.11, 6.01), three were seronegative (ratios: 1.44, 1.79, 1.85), and one was suspect (ratio: 2.17) for antibodies to *Mycoplasma* sp.

The disease that caused high mortality in this population of *T. carolina* is unknown. Necropsies on recently deceased animals often reveal the underlying cause of death (Marcus 1981). In this study, necropsy results suggest that septicemia possibly caused the death of the two individuals examined. Septicemia is a major disease syndrome in reptiles and is thought to be caused by a variety of gram-negative bacteria, particularly *Aeromonas hydrophila* and *Pseudomonas* sp. (Marcus 1981). Animals usually become infected through skin abrasions from contaminated soil or water (Marcus 1981). Septicemia is generally characterized by small hemorrhages on the skin and on mucosal and serosal surfaces (Marcus 1981). In snakes, clinical signs of this disease include respiratory distress and clear to purulent nasal discharge (Heywood 1968).

Another disease that might have caused mortality is URTD. Six of the seven *T. carolina* that died exhibited clear ocular and nasal discharge prior to death. These signs are the most common clinical signs of URTD in tortoises (Brown et al. 1994; Jacobson et al. 1991). Clear ocular and nasal discharge also were evident in a *T. c. bauri* with URTD in Florida (M. Brown, Univ. of Florida, pers. comm.). In our study, diagnosis of URTD was not possible from necropsied animals, because nasal cavities were not examined and swabbed for isolation of *Mycoplasma* sp.

Results of the ELISA tests also support the possibility that URTD might have been a factor in the deaths of turtles in this study. Three of seven turtles (47%) tested positive for antibodies to *Mycoplasma* sp., indicating that these animals had been exposed to a mycoplasma and had developed a detectable immune response. The ELISA tests, however, do not implicate *M. agassizii* as the organism causing the immune response. Therefore, it is speculative whether URTD caused by *M. agassizii* infected this population.

Iridoviruses are another potential causal agent. Members of the genus *Ranavirus* are known to cause systemic disease in infected fish and amphibians and are associated with high morbidity and mortality (Mao et al. 1997). Additionally, Mao et al. (1997) identified a *Ranavirus* sp. from a *T. carolina*. In light of this finding, the authors expressed concern that local outbreaks of iridoviruses in fish or amphibians could quickly spread to neighboring reptile populations such as box turtles. From 1997 to 2000, the period that encompassed the turtle die-off in our study, we documented mass mortality of wood frog (*Rana sylvatica*) and spotted salamander (*Ambystoma maculatum*) larvae in ponds at the study site. Necropsies of diseased amphibian larvae confirmed *Ranavirus* as the etiological agent of the mass mortality (D. Greene and K. Converse, USGS, National Wildlife Health Center, pers. comm.). However, samples from turtles have yet to be analyzed for viral infections.

Correctly diagnosing the cause of mortality in wild populations of chelonians is challenging because of a lack of detailed information on the etiology of microbial diseases and the association of secondary pathogens such as gram-negative bacteria with diseased animals. Our field data provide strong evidence for mortality due to microbial infections, but further research is needed to demonstrate specific causal agents.

Acknowledgments.—We thank R. C. Oliver at the Western Disease Diagnostic Laboratory for conducting the turtle necropsies, C. Hoggard at the College of Veterinary Medicine, North Carolina State University, for taking and processing blood samples, M. B. Brown at the College of

Veterinary Medicine, University of Florida, for interpreting serological tests and reviewing the manuscript, and D. Green and K. A. Converse at the U.S.G.S., National Wildlife Health Center, for conducting the amphibian necropsies and commenting on the impacts of iridovirus on turtles. R.B. Smith and one anonymous reviewer provided comments that greatly improved the manuscript. Funding was provided by grants from the Center for Transportation and the Environment and the North Carolina Department of Transportation.

Upper respiratory tract disease (URTD) was first described in California desert tortoises, *Gopherus agassizii*, in 1988 (Jacobson et al. 1991). Following Koch's postulate, a causative organism was soon found to be *Mycoplasma agassizii* (Brown et al. 1994). URTD is an infection known to occur in certain species of tortoises (Lawrence and Needham 1985), and more recently has been reported in natural populations of gopher tortoises, *Gopherus polyphemus* (Jacobson 1992). The symptoms of disease include, but are not limited to: serous or mucopurulent nasal discharge, epiphora, conjunctivitis, lethargy, and anorexia (Jacobson 1992). The course of the disease is usually chronic and can end in death (Jacobson 1992). This disease has received much attention in recent years because of the decline of the desert tortoise (U.S. Fish and Wildlife Service 1989) and the gopher tortoise (Auffenberg and Franz 1982) in their natural habitats. A cause and effect of disease on declining populations of gopher tortoises has not been clearly established (Smith et al. 1998). Here, we provide additional data on the occurrence of exposure of wild populations of *G. polyphemus* to *M. agassizii*.

Materials and Methods.—Destin Pipeline Company, L. L. C. (Destin) recently completed construction of a large diameter natural gas pipeline in southern Mississippi. The pipeline originates from a new offshore gathering platform in the Gulf of Mexico, travels ca. 122 km north, and makes landfall southeast of Pascagoula in Jackson Co., Mississippi. The pipeline then cuts a corridor northward for ca. 193 km in Jackson, George, Greene, Wayne, and Clarke counties to a terminus near Enterprise, Mississippi (Fig. 1).

Prior to construction, Destin was required to remove tortoises from its construction corridor (22.9–38.1 m wide) and relocate them into unoccupied gopher tortoise burrows adjacent to the right-of-way. Occupancy of burrows was determined using a camera designed for tortoise burrow inspection. These tortoises were prevented from returning to the right-of-way during construction by the use of silt fence barriers, and were monitored by biologists during construction. We collected blood samples for analysis from adult tortoises displaced from the construction of the project right-of-way (ENSR 1998). Approximately 1 cc of whole blood was taken from the brachial venous sinus or the femoral sinus. The blood was immediately placed in heparinized vacutainer tubes and placed on ice, but not frozen. The sample was allowed to separate overnight. The plasma was drawn off, placed on ice, and shipped

FIG. 1. Destin Pipeline Co. natural gas pipeline and gopher tortoise transect.

within 24 h to the Department of Pathobiology of the College of Veterinary Medicine at the University of Florida, Gainesville, for analysis. An enzyme-linked immunosorbent assay (ELISA) specific for *M. agassizii* antibody was performed on each sample (Schumacher et al. 1993).

We also collected samples from *Gopherus polyphemus* specimens immediately adjacent to the right-of-way in Jackson and George counties, where tortoises were not found on the construction corridor. By including these additional tortoises, it was possible to obtain samples from each county along a north-south transect from the Gulf Coast near Pascagoula, Mississippi to the northernmost edge of the range of *G. polyphemus* in Wayne Co., Mississippi.

Results.—A total of 26 tortoises (9 males, 17 females) were tested for exposure to *M. agassizii* (Table 1). Samples were taken from gopher tortoises in Jackson (N = 1), George (N = 4), Greene (N = 15), and Wayne (N = 6) counties. All but one tortoise tested negative for exposure to *M. agassizii* (Table 1). The test results indicated a suspect level of antibodies in tortoise #116, which showed no clinical signs of the disease. This tortoise was recaptured eight days later and tested again. The second test sample was negative.

Only one tortoise (#115) showed evidence of the clinical signs of URTD (a serous oronasal discharge). However, on 22 May 1998 it tested negative and was released. This same tortoise was later recaptured on 6 June 1998, and showed none of the symptoms previously seen. The URTD signs seen could have been related to capture stress (pers. obs.), which can easily be confused with signs of disease (McLaughlin 1997).

Discussion.—No gopher tortoises in this study tested positive for antibodies to *M. agassizii*. The sample size was small (N = 26) considering the distance of the transect (193 km). However, gopher tortoise populations are known to be sparse in the western portion of the range (Auffenberg and Franz 1982). This study is intended to provide baseline data for future monitoring of antibody levels to *M. agassizii*. This type of monitoring coupled with follow-up studies could help determine the distribution of the disease. A progressive trend toward exposure to URTD in a population would support the possibility that the disease is still spreading, and therefore might be new to *G. polyphemus*. However, if the disease is naturally occurring and essentially has always been present, then exposure and subsequent immune responses might have reached a balance in natural populations.

Like many other diseases, there might be more than one causative organism and other factors might be involved in producing URTD (Diemer Berish et. al. 2000). One such question is the role of *Pasturella* sp. and other gram-negative organisms in the disease process (Jacobson 1992). Certain organisms act synergistically to produce disease and consequently the presence of other species of bacteria could affect the severity of the disease. It is also likely that factors resulting in stress such as drought, starvation, and habitat degradation play an important role in the disease process (Jacobson 1992). Therefore, it is important to realize that a positive ELISA test for *M. agassizii* in tortoises simply indicates the animal has been exposed to the organism and now has antibodies against it. A positive test does not equal a positive URTD status.

URTD is an important disease within certain tortoise populations. It has been known to affect large portions of *G. agassizii* populations (Jacobson et al. 1991) and has been associated with high mortality rates. Within the past decade, antibodies against *M. agassizii* have been found within free-ranging gopher tortoise populations (Diemer Berish et al. 2000; Smith et al. 1998). The long-term effect URTD will have on tortoise populations is still unknown. Although Smith et al. (1998) found 100% exposure to URTD in a wild population of *G. polyphemus* in Mississippi, we found 0% in our study. The question of how populations of *G. polyphemus* become exposed to *M. agassizii* is fundamental and necessary to understanding how to manage tortoise populations in the future. Whereas Smith et al. (1998) recorded data from a population of tortoises in a protected wildlife management area, we recorded our data from tortoises scattered across the range, mostly from isolated individuals or small groups. Smith et al. (1998) postulate that a possible source of infection in their study might have been the introduction of an infected individual or individuals and that the disease might be spreading to uninfected populations. If this is the case, the incidence of URTD infection in Mississippi might still be restricted to certain populations or regions. Regarding the management of free ranging tortoises, some researchers have recommended not releasing previously-ill tortoises or tortoises having a positive titer to *M. agassizii* back into their natural range, thereby preventing spread of disease or introduction to naive populations. This strategy might only be prudent if the infection is introduced. However, if it occurs naturally, and outbreaks occur sporadically in populations, then logic would suggest that

TABLE 1. Gopher tortoises (*Gopherus polyphemus*) tested during 1998 for upper respiratory tract disease (URTD) in Mississippi.

* tested negative on 4 June

recovered individuals could be returned or translocated to natural populations. We hope that data regarding the exposure of free ranging tortoises to *M. agassizii* will be helpful in answering some of these questions.

that the group was composed of 2.2 adults is correct, then two females are capable of producing at least 61, and possibly more, offspring in a single breeding season

Hatchlings are capable of attaining near adult size in less than a year (Fig. 1). Growth rates of the sirens maintained indoors at a relatively constant temperature of 25–27°C were greater than those maintained outdoors and subjected to seasonal fluctuations in temperature. As far as we could determine, the density of hatchlings per enclosure had little effect on growth and mortality as long as there was adequate supplemental feeding.

Wild-caught *Pseudobranchus s. striatus* collected as juveniles reproduced in their fourth year. Captive conditions in earlier years might not have provided appropriate stimulus for reproduction. Nevertheless, F_1 offspring kept under identical conditions to those under which the adults bred had not yet reproduced by their third year. Two of the six original, wild-caught sirens, presumed to be 1.1, were continually housed indoors in a transparent plastic aquaria. To facilitate observation, the aquaria were maintained with clear water, few plants, and only a gravel substrate. Although this arrangement apparently did not compromise husbandry, no attempts at reproduction were ever observed. The oviposistion period for *P. striatus* was mid-June through August. The oviposition period for wild *P. axanthus* is reported to last from early November through March (Petranka 1998). The maximum length attained by a captive-raised *P. striatus* is 230 mm TL, slightly exceeding the published maximum length of 220 mm (Petranka 1998). No published data regarding longevity of *Pseudobranchus* could be found. At RZG, two captive-raised *P. s. striatus* are seven years old at the time of writing and still alive.

Unfortunately, conditions that stimulated reproduction in *Pseudobranchus*, e.g. turbid water, dense mats of vegetation and substrate, also prevented ready observation of some behaviors such as courtship and fertilization. Searching for eggs and offspring involved draining the tank, capturing the sirens and sorting through the vegetation and substrate. It was believed that this level of disturbance might compromise animal health and inhibit reproduction, hence frequent and continuous observations were not made. Nevertheless, these might represent the only observations for size and age at first reproduction as well as growth, fecundity, oviposition, and longevity for this species.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send two copies of manuscripts, double-spaced, directly to the appropriate section co-editor (addresses on inside front cover): Marc P. Hayes (lizards, amphisbaenians, crocodilians, *Sphenodon*); Charles W. Painter (amphibians); or Brian Butterfield (snakes, turtles). Authors are requested to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a Rich Text Format (RTF) version of the file. Alternatively, authors may submit manuscripts electronically, as e-mail attachments. Figures can also be submitted electronically as JPG files, although higher-resolution TIFF files may be requested for publication.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother (2000. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*. Herpetol. Circ. 29:1–82); for Mexico as it appears in Liner (1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herpetol. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

AMBYSTOMA LATERALE (Blue-spotted Salamander) and ***AMBYSTOMA MACULATUM*** (Spotted Salamander). **PREDATION**. Predation by wood frog (*Rana sylvatica*) tadpoles on *A. maculatum* egg masses has been described in detail (Petranka et al. 1995. Herpetologica 54:1–13). However, nothing has been written on *R. sylvatica* predation on *A. laterale*. In Maine, all three species commonly breed in the same temporary woodland pools, where *R. sylvatica* hatch first, then *A. laterale*, then *A. maculatum*. *Ambystoma laterale* masses have fewer eggs, and are encased in jelly that is less dense than that of *A. maculatum* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.).

On several occasions during Spring 2001, in woodland ponds in northern and central Maine, we observed *R. sylvatica* behavior that suggested preferential predation on egg masses of *A. laterale* over those of *A. maculatum*. A single predation event witnessed in captivity confirmed that *R. sylvatica* does attack and ingest larval *A. laterale*.

On 7 May 2001 between 1655 and 1725 h, two observers counted all egg masses in an approximately 900 m^2 temporary pool (44°57.72'N, 68°32.61'W) in Sunkhaze Meadows National Wildlife Refuge, Maine, USA. Average counts of two observers resulted in the following estimated egg mass numbers: *A. maculatum* (372), *A. laterale* (260), and *R. sylvatica* (172). Many of the *R. sylvatica* masses had already hatched. We observed *R. sylvatica* tadpoles "swarming" around egg masses of *A. laterale*. The same behavior was not observed on masses of *A. maculatum* eggs. Swarming consisted of many tadpoles on and inside a mass, some making violent, alternating, side-to-side motions of the head and body, apparently tearing at the egg mass. This behavior was much more active than typical algae grazing behavior. We observed several tadpoles using the same behavior eating tissue of a dead, submerged gray tree frog (*Hyla versicolor*). In contrast to their abundance on *A. laterale* egg masses (50+/egg mass), we observed very few on or near the *A. maculatum* egg masses in the pond and none of the tearing motions.

Similar behavior was observed on 15 May in a pool ca. 200 miles north, and a week later at a third pool close to the first. Between 1355 and 1500 h on 15 May at 44°11.89'N, 68°39.28'W one observer counted 128 *A. maculatum* egg masses and 546 *A. laterale* egg masses. *Rana sylvatica* had recently emerged. Another observer counted 132 egg masses prior to hatching. Again, *R. sylvatica* were observed in great numbers around *A. laterale* egg masses (with some penetrating the interior), and in small numbers at *A. maculatum* masses. On 22 May at 44°53.17'N, 68°41.11'W, the same behavior was observed. On 5 May, at this same pool, 705 *A. laterale*, 22 *A. maculatum*, and 82 *R. sylvatica* egg masses were counted.

Observations in captivity confirmed that *R. sylvatica* does ingest newly emerged *A. laterale* larvae, and suggest differences in composition of the ambystomid egg masses that might explain this differential predation observed in the field. On 11 May, *R. sylvatica* tadpoles, newly emerged *A. laterale*, *A. laterale* egg masses (ca. stage 37) (Harrison 1969. Organization and Development of the Embryo. Yale University Press, New Haven. 290 pp.) and 2 *A. maculatum* egg masses were placed in a light colored basin for close observation. Almost immediately, a tadpole was observed ingesting a larval *A. laterale*. The *A. laterale* eggs within the masses were a much brighter shade of green (denser concentration of algae) than those of *A. maculatum*.

Thanks to the U.S. Fish and Wildlife Service and the Department of Plant, Soil, and Environmental Sciences, University of Maine for Spring 2001 field support.

Submitted by **ROBERT F. BALDWIN** and **ARAM J.K. CALHOUN**, Department of Plant, Soil, and Environmental Sciences, University of Maine, Orono, Maine 04469, USA; e-mail: (RFB): rob_baldwin@umenfa.maine.edu.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). **REPRODUCTION**. Observations on nesting of *Hemidactylium scutatum* have indicated an overall seasonal progression from south to north (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Instit. Press, Washington, D.C. 587 pp.). On 4 Feb 2001 in Jasper County, Georgia, we discovered three female *H. scutatum* communally nesting in a moist, rotten log overhanging shallow water at the edge of a beaver pond. The locale, Monticello Glades, Oconee National Forest (33°14'N, 83°42'W), is on the lower Piedmont Plateau of Georgia, and is a complex of marsh, shrub, and forested wetlands immediately surrounded by upland hardwood forests, some mixed with pine. Sphagnum moss is scarce within the complex. Insofar as we can determine, this is the earliest range-wide date for which nesting has been recorded for this species (Petranka, *op cit.*). Additionally, it is the first record of *H. scutatum* nesting in Georgia. Communal nesting appears to be common for this species throughout much of its range (Petranka, *op cit.*).

In addition to the nesting females, several other individuals were observed underneath logs in the immediate vicinity. One female was photographed beside the communal nest. The photograph was deposited in the Georgia Museum of Natural History (GMNH 46761). This individual and one other (GMNH 46762; both verified by M.E. McGhee) represent the first vouchered records for *H. scutatum* in Jasper County (Williamson and Moulis 1994. Distribution of Amphibians and Reptiles in Georgia. Savannah Science Museum Special Publication No. 3. 712 pp.).

SMITH**, Warnell School of Forest Resources, University of Georgia, Athens, Georgia 30602, USA (e-mail: ascaphus@mindspring.com), and **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA.

PLETHODON GLUTINOSUS (Slimy Salamander). **TREE CLIMBING**. Observation of climbing activity in *Plethodon glutinosus* is limited to reports describing rocky substrates (Brode and Gunter 1958. Herpetologica 13:279–280; Cliburn and Porter 1986. J. Mississippi Acad. Sci. 31:91–96). However, we observed plant climbing by this species at a barrow pit east of Westall Swamp (35°24'N, 86°05'W), Arnold Engineering and Developing Center (AEDC), Coffee County, Tennessee, USA. On the evening of 4 June 2001 at 2230 h, we discovered an adult *P. glutinosus* on the limb (19 cm diameter) of a mature loblolly pine (*Pinus taeda*) at a height of 53 cm. The air temperature was 22°C. The forest floor litter, tree limbs, and leaf surfaces were wet following a brief period of rainfall that ended less than an hour before our arrival, thus our observation supports Jaeger's (Copeia 1978:686–691) conclusion that plant–climbing activity occurs almost exclusively during wet nights. With the aid of its prehensile tail, *P. glutinosus* frequently ascends cavern walls (Brode and Gunter, *op. cit.*) and enters sandstone cliff crevices using near-horizontal connections with the base of the cliff (Cliburn and Porter, *op. cit.*). Although the salamander might have vertically ascended the trunk to its position on the limb, the end of the arched limb contacted the ground ca. 4 m from the base of the tree and also provided a sloped, near horizontal, route of entry.

ANURA

ELACHISTOCLEIS ERYTHROGASTER (Red-bellied Oval Frog). **DEFENSIVE BEHAVIOR.** *Elachistocleis erythrogaster*, a small microhylid endemic to the southeastern *Araucaria* plateau of Rio Grande do Sul, southern Brazil, was recently described by Kwet and Di-Bernardo (1998. Stud. Neotrop. Fauna Environ. 33:7–18). On 15 January 2001, six *E. erythrogaster* were collected at a pond near the CPCN Pró-Mata reserve, municipality of São Francisco de Paula, Rio Grande do Sul (960 m elev.). They were carried to the laboratory and kept in a terrarium. On 18 January, one individual was placed on a wooden table to be photographed. Immediately, the frog inflated its lungs, stretched out the hindlimbs and elevated the posterior part of the body. This posture was maintained for about one minute and it was possible to trigger this behavior several times by touching lightly. Of the six specimens tested, five demonstrated this defensive behavior when handled.

The antipredator behavior of presenting a larger image to potential predators is common among heavy-bodied anurans, although this is the first record for a New World microhylid. Puffing up the body and outstretching the limbs makes *E. erythrogaster* larger and should help protect against ingestion. Additionally, this microhylid produces a whitish, sticky skin secretion that might be toxic to predators. When handled, *E. erythrogaster* did not expose the aposematic ventral coloration consisting of bright red or orange-red spotted with black; therefore the function of the red and black ventral coloration remains unclear.

We thank Wolf Engels, Marcos Di-Bernardo, and Andreas Schlüter for support.

ELEUTHERODACTYLUS COQUI (Puerto Rican Coqui). **IMMOBILIZATION.** The plant *Urera baccifera* (Urticaceae) is a common nettle in the rain forest at the El Verde Field Station (350–400 m elev.) in the Luquillo Mountains of northeastern Puerto Rico. When touched by humans it produces minor irritation and itching. Both leaves and stems are covered with stinging thorns, which are ca. 3–4 mm in height on the upper surface of the leaves. Extracts of this plant have known acute toxicities in mice and rats (Badilla et al. 1999. Revista de Biologia Tropical 47[4]:723–727). I (GRT) have observed *E. coqui* for many years in the Caribbean National Forest surrounding the El Verde Field Station and have rarely seen *E. coqui* or other vertebrates on this plant. When I have observed frogs that have either accidentally jumped or fallen on this plant, they immediately leap off.

On the evening of 29 May 2001 at 2250 h in the forest 0.5 km northeast of the El Verde Field Station, we found an adult male *E. coqui* immobilized on the upper leaf surface of *U. baccifera*. When we approached, the frog was unresponsive, and remained stationary with its ventral surface flat to the leaf. Furthermore, it did not move when touched on its dorsum. After approx. one minute, the frog was gently removed from the leaf and it was immobilized. This state of immobility lasted for 3–4 minutes. After this time, the frog jumped into the forest vegetation. When we tried to capture it, it appeared to be functioning normally, and jumped upon detecting our approach. Steward (1985. J. Herpetol. 19:391–401) noted that *E. coqui* parachutes or falls from trees to the ground. Therefore, *U. baccifera* could be a potential hazard, possibly causing injury or death via immobilization. Further, if parachuting frogs were impaled on its thorns, they could be vulnerable to predation. Although Steward (*op. cit.*) reported no instance of *E. coqui* landing on this plant, we believe that this poses potential danger. It is not clear whether this immobilization was the result of the plant's chemical toxin, shock from the fall, or other consequences. However, because *E. coqui* is rarely seen on *U. baccifera*, and the plant has physically threatening spines with a known irritant, we conclude that immobilization was the result of abusive contact with *U. baccifera*.

We thank the staff of the El Verde Field Station for the use of their facilities. The El Verde Field Station is part of the Long Term Ecological Research Project funded by the National Science Foundation.

HYLA NANA (Dwarf Tree Frog). **PREDATION**. Metamorphosing anurans are common prey for a variety of vertebrate and invertebrate predators. Spiders have been considered one of the most important predators of small terrestrial anurans (Hayes 1983. Biotropica 15:74–76) and numerous authors have reported them feeding on metamorphosing and adult hylid frogs.

On 27 Nov 2000 at 2300 h, we collected a *Hyla nana* metamorph at a swamp located in the Department of Itapúa, Alto Vera, San Pedro Mí, Paraguay (26°31'25"S, 55°48'19"W). The *H. nana* (TL ca. 10 mm) was being eaten by a juvenile spider (cephalothorax-abdomen length ca. 12 mm) of the genus *Thaumasia* (Araneae:

FIG. 1. A pisaurid spider, *Thaumasia* sp., shown with *Hyla nana* metamorph, following preservation.

Pisauridae). At the time of collection, the spider had the frog in its jaws and was sitting ca. 30 cm above the water on vegetation growing at the perimeter of the swamp. The frog was dead upon discovery and continued to dissolve prior to preservation. Both specimens were collected and deposited at the Museo Nacional de Historia Natural del Paraguay (MNHNP, CR [counter reference] #2061). The spider and the remaining frog prey were photographed after preservation (Fig. 1). To our knowledge, this is the first account of a pisaurid (*Thaumasia* sp.) feeding on a metamorph *H. nana*.

We thank J. Simmons and Nancy Lopez de Kolchalka for directing the KUNHM BRC and the MNHNP participation in a herpetofaunal survey of the Reserva de San Rafael and L. Trueb for reading an earlier draft of this note. We also thank J. Kochalka of MNHNP for identifying the spider.

LEPTODACTYLUS FUSCUS (NCN). **PREDATION**. Snakes of the genus *Liophis* are known to prey upon frogs, including species of *Leptodactylus* (Michaud and Dixon 1989. Herpetol. Rev. 20(2):39–41). Herein is the first report of *Liophis meridionalis* feeding upon *Leptodactylus fuscus* that we are aware of. On 7 Dec 2000 (1500 h), at Clube Caça e Pesca Itororó de Uberlândia (Uberlândia, Minas Gerais, Brazil: 18°59'S 48°18'W), workers cleaning the grasses around a dry pond killed a snake while it was preying on a frog. We identified the snake as an adult female *Liophis meridionalis* (610 mm SVL; UFU 1107, Museu de Biodiversidade do Cerrado, Universidade Federal de Uberlândia) and the frog as an egg-bearing female *Leptodactylus fuscus* (45 mm SVL; AAG-UFU 2250). In the laboratory we examined the digestive tract of the snake and found two feet of other adult *L. fuscus*. In the summer, adult *L. fuscus* congregate around ponds to reproduce, and if conditions are not appropriate for egg laying, the females might wait for rains, thus becoming more susceptible to predation by snakes.

PHYLLOMEDUSA ATELOPOIDES (Purple Leaf Frog). **REPRODUCTION**. Little is known about the natural history of many recently discovered neotropical frogs. The recently described *Phyllomedusa atelopoides* is the only terrestrial member of the arboreal hylid subfamily Phyllomedusinae. Arboreal phyllomedusine frogs typically lay their eggs on leaves above forest pools, however only one clutch of *P. atelopoides* has been reported (Duellman et al. 1988. Herpetologica 44:91–95). Herein we report new observations on reproduction in *P. atelopoides*.

Observations were made during the rainy season from 28 Dec 2000 to 14 Jan 2001 in the seasonally dry rainforest of the Reserva Cuzco Amazónico on the north bank of the Río Madre de Dios, ca.15 km ENE of Puerto Maldonado, Departamento Madre de Dios, Peru (see Duellman and Koechlin 1991. Occas. Pap. Mus. Nat. Hist. Univ. Kansas 142:1–38). An amplectant pair of *P. atelopoides* was discovered by eyeshine at 2300 h on 29 Dec 2000. The pair was located in terra firma forest, ca. 10 m W of Trail B ca. 750 m from Cuzco Amazónico lodge. The nesting site was ca. 20 m east of a slow moving stream, the Quebrada Mariposa. The amplectant pair was laying eggs and wrapping them in a leaf on a short (ca. 30 cm) herbaceous plant with 3 leaves. The plant was isolated from other low-lying vegetation by ca. 2 m, but was under an enclosed tree canopy. The nesting plant was located on the bank, ca. 30–45 cm from water's edge of a small (1 m x 2.5 m), shallow (ca. 30 cm max. depth), temporary pool. The adult frogs were gone at 2400 h and could not be found. Two days later (31 Dec) at 1700 h, the leaf enclosing the eggs was opened to reveal 25 yellow eggs adhered to the leaf in a clear gelatinous-like substance. The leaf was then closed. By 3 Jan 2001 the nest remained intact but the pool had completely disappeared, with only wet earth remaining. The eggs were present and showed signs of development at 1620 h on 8 Jan. On the following day (9 Jan) at 2148 h only 9 eggs remained, and on 10 Jan the leaf was found open with only two eggs remaining.

These observations are consistent with those reported previously for *P. atelopoides* and corroborate their terrestrial habitat preference. This species has never been reported to be more than 30 cm above the ground, and the only other observed amplectant pair was laying unpigmented eggs in a wrapped leaf 5 cm above the ground at the edge of a shallow pool (Duellman et al., *op. cit.*). The clutch size reported herein of 25 eggs is close to the number reported for the only previously known clutch that had 20 eggs (Duellman et al. *op. cit.*). We suspect that the disappearance of the eggs was not because of hatching. When last observed, development of the eggs was not very advanced and only twelve days had elapsed since they were laid. Furthermore, there was no evidence of hatchlings in the vicinity. We suspect that the disappearance may have been the result of predation, as snakes (e.g., *Leptodeira* spp.) are known to prey on phyllomedusine clutches.

This work was funded in part by a University of Wisconsin-Stevens Point University Personal Development Committee Grant and a College of Letters & Sciences Foundation Grant, both to ERW.

Submitted by **JOEL E. BLOCK, JULIE K. MOONEY, STACEY L. UNSER,** and **ERIK R. WILD**, Department of Biology, University of Wisconsin-Stevens Point, Stevens Point, Wisconsin 54481-3897, USA; e-mail (ERW) ewild@uwsp.edu.

PHYSALAEMUS BILIGONIGERUS* and *PHYSALAEMUS GRACILIS (Weeping Frog and Graceful Dwarf Frog). **REPRODUCTIVE BEHAVIOR.** In contrast to explosive breeders, in anurans with a prolonged breeding season males typically remain stationary at calling sites waiting for females. In such lek-like mating systems, females move through choruses and freely select mates with little interference from males. Therefore, heterospecific amplexus is rarely found in nature in species with female choice. Herein I report amplexus between specimens of two species of lek-breeding dwarf frogs of the genus *Physalaemus*.

On 25 December 1997 at 2300 h, I observed an amplectant pair of a male *P. gracilis* (Stuttgarter Museum für Naturkunde, Germany, SMNS 9190) and a female *P. biligonigerus* (SMNS 9189) at a flooded pasture near Lamí, municipality of Porto Alegre, Rio Grande do Sul, southern Brazil. At this locality, males of both species were calling. The heterospecific pair was photographed and carried to the laboratory. During the night, the frogs maintained the axillary amplexus but did not construct a foam nest as frequently observed in conspecific pairs of this genus kept together in a small container. Next morning both specimens were separated. Although the dissected female contained eggs, no spawning had occurred. *Physalaemus gracilis* and *P. biligonigerus* are morphologically different species, belonging to different species groups. However, they possess similar advertisement calls that are nearly indistinguable to the untrained human ear. It may be assumed that the female *P. biligonigerus* was misled, being attracted by the call of the heterospecific male *P. gracilis*. Although call discrimination by the females of these species may not always function, I found no evidence of hybridization.

Submitted by **AXEL KWET**, Zoologie, Staatliches Museum für Naturkunde Stuttgart, Rosenstein 1, D-70191 Stuttgart, Germany; e-mail: axel.kwet@uni-tuebingen.de.

PSEUDACRIS BRACHYPHONA (Mountain Chorus Frog). **VERIFICATION OF HISTORICAL OCCURRENCE.** The last confirmed record of *Pseudacris brachyphona* within North Carolina was on 20 February 1954: North Carolina State Museum (NCSM 11123–11125); Charleston Museum (Ch.M. 54.32.11). However, on 25 and 26 February and 9 March 2001, several choruses were observed within Cherokee County, North Carolina (35°02'30"N, 84°03'08"W). Males were observed calling from a flooded roadside ditch adjacent to an upland slope containing *Pinus virginiana* and *P. echinata*. *Juncus* sp., *Andropogon virginicus*, and other vegetation were growing within the roadside ditch. Males were seen calling from the base of vegetation at or slightly above the surface of the water. Calling males were also observed within an adjacent, regularly cut field that contained temporary puddles near a small stream. These temporary puddles were sparsely vegetated and had fine woody debris and bark along the margins. Males were seen calling among the debris. *Pseudacris crucifer* were often heard calling with *P. brachyphona*. Clemson University (CUSC 987 [vocal recording: accession # 987]; specimen photographs: catalog #s 2065, 2066). H. LeGrand (North Carolina Natural Heritage Program) and J. Beane (NCSM) provided documentation of the last confirmed report of *P. brachyphona* within North Carolina.

Submitted by **THOMAS M. FLOYD** and **ERAN S. KILPATRICK**, 261 Lehotsky Hall, Box 340331, Department of Forest Resources, Clemson University, Clemson, South Carolina 29634-0331, USA; e-mail (TMF): tfloyd@clemson.edu.

PSEUDACRIS CRUCIFER (Spring Peeper). **PREDATION.** Observations of predation on *Pseudacris crucifer* have identified odonate and beetle larval or nymphal stages, fish, and salamanders as predators of tadpoles (e.g., Skelly 1996. Copeia 1996:599–605), and snakes as predators of adults (e.g., Rowe et al. 2000. Herpetol. Nat. Hist. 7:145–152). Little is known about predators on metamorphs. On 21 June 2001 at 0830 h, I observed a ground beetle (*Scarites subterraneus*: Carabidae) consuming a metamorph *P. crucifer*. The beetle and metamorph were found under a board near a temporary pond in the Taylor-Ochs section of the Denison University Biological Reserve, Granville, Licking County, Ohio. This observation suggests that terrestrial insects may be a potentially overlooked source of mortality for metamorphic anurans.

Submitted by **GEOFFREY R. SMITH**, Department of Biology, Denison University, Granville, Ohio 43023, USA; e-mail: smithg@denison.edu.

SCINAX CRUENTOMMA (NCN). **PREDATION.** Although some information is available concerning the predation of frogs, fewer data exist concerning species-specific predators. Herein we report an adult *Scinax cruentomma* (Hylidae) being preyed upon by a wolf spider (Lycosidae). This small (25–31 mm) frog is generally found in forests and clearings, and breeding occurs in temporary pools where males call from leaves or blades of grass above the water (Rodriguez and Duellman 1994. Guide to the Frogs of the Iquitos Region, Amazonian Peru, Asociacion De Ecologia Y Conservacion. 48 pp.).

On 9 May 2000, at 2130 h, a breeding aggregation of ca. 50 *S. cruentomma* was discovered at the ExplorNapo Lodge Reserve ca. 75 km northeast of Iquitos, Departamento Loreto, Peru. The individuals were in flooded forest adjacent to the Guebrada Grande on the western border of the reserve.

A single adult *S. cruentomma* was observed as it was being consumed by a large wolf spider on the side of a small tree ca. 1 m above the ground. When disturbed, the wolf spider carried the frog underneath a log.

Submitted by **BRIAN AUCONE** and **WINSTON CARD**, Dallas Zoo, Department of Herpetology, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA; e-mail (BA): herper1@hotmail.com.

TESTUDINES

CARETTA CARETTA (Loggerhead Sea Turtle). **NESTING BEHAVIOR**. The general nesting process is essentially the same in all species of sea turtles, including the steps involved in excavating the egg chamber. Using her rear flippers, the female turtle typically digs a flask-shaped egg chamber with a narrow neck and wider bottom. The turtle accomplishes this excavation through a methodical series of steps that result in a single-chambered egg chamber with a single opening at the top (Hailman and Elowson 1992. Herpetologica 48:1–30). Variations in the shape of the egg chamber are observed most often in response to variations in sand type (Miller 1997. *In* Lutz and Musick [eds.], The Biology of Sea Turtles, pp. 51–81. CRC Press, Inc., Boca Raton, Florida), however the general shape of one egg chamber with one surface opening is consistent. A nest of two conjoined egg chambers with one common opening has previously not been reported. During the 1997 nesting season, however, researchers with the University of Florida's Cooperative Fish and Wildlife Research Unit observed

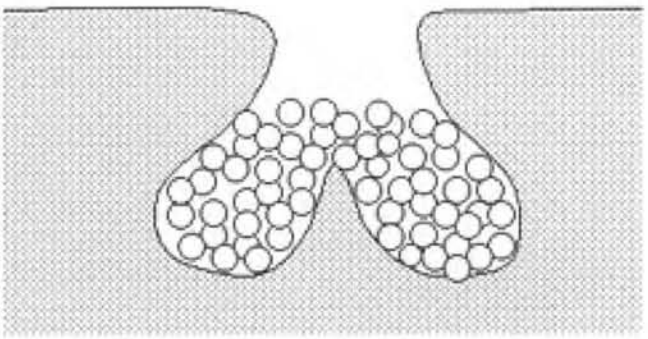

FIG. 1. Diagrammatic representation of double-chambered nest of *Caretta caretta* from Cape San Blas, Florida.

two loggerhead sea turtle (*Caretta caretta*) nests that each had two conjoined egg chambers with a single common opening (Fig. 1). Discussions of this phenomenon with other sea turtle monitoring groups in Northwest Florida revealed that double-chambered nests had been observed on four other occasions on panhandle nesting beaches.

Since 1994, the UFL Coop Unit has been conducting daily morning nesting survey along three miles of beach owned by Eglin Air Force Base (EAFB) on Cape San Blas, Florida, USA. Surveys are conducted on foot or all-terrain vehicles, and data are collected on false and nesting crawls. Nests threatened by erosion or water inundation are relocated to a more protected site along the EAFB beach. Nests are screened and staked to prevent depredation and marked with signs and flagging. Incubating nests are monitored daily for signs of hatchling emergence and are excavated to determine hatching success 72 hours after emergence or after 85 days of incubation.

During the 1997 nesting season, two separate nests possessing double-chambered egg chambers were observed at Cape San Blas. On 3 July 1997, at 0635 h, a *C. caretta* nest (designated as nest 33) was located at mile marker 2.55 along the north beach of EAFB property on Cape San Blas. Due to threats of water inundation and erosion, the nest was relocated. While excavating the nest for relocation, it was observed that the nest had two egg chambers connected with one common opening. Eggs were located in both sides and in the common neck of the chamber. Several weeks later it became apparent that this had not been a unique event along Cape San Blas. On 20 June 1997, a *C. caretta* nest (designated as nest 15) was located at mile marker 2.56 along the north beach and 60 eggs were relocated to the east beach. At the time of excavation it was noted that the egg chamber was narrow and tilted to one side. On 20 August 1997, while obtaining GPS coordinates for the original site of nest 15, eggshells and hatchling tracks were observed. Upon investigation, it was determined that nest 15 also had a double egg chamber, but only one side of the chamber had been discovered originally. One half of the nest (containing 36 eggs) had inadvertently been left *in situ* along the north beach (15a), and the other half had been relocated to the east beach (15b).

There are four other known occurrences of double-chambered nests in Northwest Florida between 1996 and 1998. In 1996, a double-chambered nest was found on St. Vincent Island (reported by Thom Lewis, St. Vincent National Wildlife Refuge) that contained 106 eggs, with 30 in one chamber and 76 in the other. In 1997 a double-chambered nest was found during hatching success evaluation on the St. Joseph Peninsula (reported by Joe and Carolyn Hooper, Gulf County Turtle Patrol) only a few miles north of Cape San Blas. This nest contained 96 eggs with 34 in one side and 60 in the other. Two double-chambered nests were found on Panama City Beach during the 1998 nesting season (reported by Martha Maglothin and Bob Gilmore, St. Andrew Bay Resource Management Association). The first nest was found on 29 May and contained 159 eggs. The distribution of the eggs between the two chambers is unknown. The second nest was found on 13 June and contained 142 eggs with 79 in one chamber and 63 in the other. Hatching success for each of the double-chambered nests is summarized in Table 1.

Upon examination of the data from the nests at Cape San Blas, it appears the same turtle laid both double-chambered nests. The primary difference between the two nests was crawl width, which could be attributed to variation in weather and sand conditions. The 13-day inter-nesting period and the proximity of the two nests are supportive of the theory that a single female laid both nests. It is also possible that this same female laid the double-chambered nest found on St. Joseph Peninsula on 28 July 1997. Similarly, the 14-day period between the laying of the double-chambered nests found on Panama City Beach in 1998 indicates one female may have been responsible for both.

It is unknown how female turtles dug the double-chambered egg chambers. The shape of a sea turtle's egg chamber is influenced by several factors including buried debris, variations in substrate, and flipper physiology and function (Miller, *op. cit.*). Because the nests described were laid in close geographic proximity to typically shaped nests, debris and substrate variations appear to have had little influence. Also, the shape of each individual chamber within the double-chambered nests was typical, and the crawls had a normal appearance. Therefore, it does not seem likely that this situation could be attributed to abnormal shape in the rear flippers. The depth/length of the dual chambers seemed to indicate no truncation of flipper length, however this cannot be ruled out as a mechanism without direct observation of the animals. Most likely, the double-chambered egg chambers are a result of abnormal function of the rear flippers. Normal digging is accomplished by reaching inward and scooping outward. The right rear flipper is placed into the hole

TABLE 1. Hatching success of double-chambered *Caretta caretta* nests in Florida.

Location	Nest Number	Date Laid	Date Hatched	Percent Hatching
St. Vincent Island	9637	17 July1996	—	0.0
Cape San Blas	15a	20 June 1997	19 August 1997	97.2
Cape San Blas	15b	20 June 1997	20 August 1997	90.0
Cape San Blas	33	3 July 1997	30 August 1998	72.7
St. Joseph Peninsula	H110	28 July 1997	25 September 1997	97.9
Panama City Beach	1	29 May 1998	26 July 1998	59.0
Panama City Beach	7	13 June 1998	10 August 1998	56.0

medially and used to scoop downward, forward and to the left. The right flipper excavates the left side of the hole and the left excavates the right side. The observed digging aberration could be achieved by the female shifting laterally to a greater degree as she places her flippers into the hole, and allowing a "septum" to develop between the digging efforts of the two flippers. This may result from a behavioral or kinesiological deviation by the nesting female.

Hatching success indicated that eggs laid in the double-chambered nests had no greater disadvantage than those laid in a typical single-chambered nest. Whatever abnormality the female turtle had did not prevent her from laying viable eggs. In nest 15, eggs left in the original nest had hatching success comparable to eggs that were relocated; indicating the structure of the individual chambers within each nest was adequate for successful incubation and hatching conditions. Although double-chambered nest construction appears to be anomalous, there may be adaptive value in this pattern of egg deposition. Nest predators may be fooled into excavating only one side of the cavity, as were the researchers. Lack of observed deleterious effects from the clutch splitting enhances the usefulness as a possible strategy to limit predation and maximize production.

We thank Thom Lewis, Joe and Carolyn Hooper, Bob Gilmore, and Kennard Watson for contribution of their observations. We also thank personnel at Eglin Air Force Base, particularly Carl Petrick, Bruce Hagedorn, Dennis Teague, Debby Atencio, and B.A.E. Systems (formerly Vitro Technical Services) for support throughout this project. Research was conducted under Florida Department of Environmental Protection Permit number TP#094.

LACERTILIA

AMEIVA ALBOGUTTATA (Mona Island Ameiva). **ARBOREAL ACTIVITY**. Lizards in the genus *Ameiva* commonly are characterized as actively foraging ground-dwellers (e.g., Sproston et al. 1999. J. Herpetol. 33:131–136). However, on 19 October 1999 near Playa Sardinera, Isla Mona, one of us (RP) observed a juvenile *A. alboguttata* 4 m above the ground on the trunk of an Australian Pine (*Casuarina equisetifolia*). At 4 m, the trunk diameter was ca. 60 cm. With binoculars it was evident that this lizard was following an ant trail, periodically taking a prey item while continuing to climb until it disappeared in foliage at a height in excess of 6 m. Careful examination around the base of the tree (to > 2 m) failed to reveal the presence of ants. This observation suggests that these typically terrestrial lizards may occasionally (and intentionally) climb in order to exploit food resources not readily available or evident at ground level. We are unaware of any published accounts of *Ameiva* climbing to find food, but one of us (EJC) has observed adult *A. corax* on Little Scrub Island feeding on prickly pear cactus flowers and fruits at heights approaching 2 m and *A. plei* on Anguilla ascending tree trunks to heights of ca. 1 m in search of land snails.

Miguel A. Garcia, Department of Natural Resources, Puerto Rico, facilitated the visit by RP to Isla Mona in association with the West Indian Iguana Specialist Group.

CENSKY**, Connecticut State Museum of Natural History, University of Connecticut, Storrs, Connecticut 06269, USA (e-mail: censky@uconnvm.uconn.edu).

EMOIA CAERULEOCAUDA (Pacific Blue-tailed Skink). **BEHAVIOR**. Males of *Emoia caeruleocauda* exhibit a high frequency of intraspecific conflicts in captivity (McCoid et al. 1997. Herpetol. Rev. 28:202; Porej, unpubl. data), which often lead to injuries and death. Here I report observations on display and combat behavior in male *E. caeruleocauda* in the wild. Observations of adult male *E. caeruleocauda* were made on the island of Rota in September 1999, on a wide, sunny concrete support wall at the Teteto Beach. An adult male approached another basking male to a distance of ca. 40 cm, and both individuals started head-bobbing with their tails slowly waving. After less than 10 s both individuals highly arched their backs, and started to rapidly flick their tails. This was followed by a series of ca. 25 short, side-to-side and forward bouncing jumps with all four limbs fully extended. As they approached each other, they turned more and more sideways until they were facing away from each other, with their tails almost touching. Then they slowly backed toward each other such that their slowly waving tails were directly over their opponent's head. When one of the combatants would bite the opponent's tail the other lizard would spin and bite its now exposed head or neck. A melee would then ensue, which lasted until the lizard bitten on the neck broke the grip on its neck. At that point the combatants would assume their original positions. This sequence repeated four times, except for the initial head bobbing which was not observed again.

The conflict was interrupted twice by other *E. caeruleocauda*, which were not collected, but whose sex I am inferring from their size, color pattern, and head width. In field conditions, males of *E. caeruleocauda* can be distinguished from females by their larger maximum SVL (52.8 mm males, 47.8 mm females), loss of yellow dorsal stripes and blue tail coloration in larger males (the largest striped male had a SVL of 43 mm in my sample of 253 individuals from Rota), and broader heads. Based on the same sample, regression analysis indicates that males have significantly broader heads (measured at the widest point) than females ($p<0.0001$, two-sided t-test), and the difference in the means after accounting for body size is estimated to be 0.74 mm (0.62–0.86 mm, 95% C.I.), which is 15–18% of the average female head width.

The first inquisitive individual was considerably smaller than the two combatants, was blue-tailed and striped with a relatively narrow head and thus assumed to be a female. Although it came very close to the two combatants, and at one point even passed between them, they appeared to ignore it. The second individual to approach the combatants was only slightly smaller than the two of them, but had a broad head and was uniform gray in dorsal coloration and thus, assumed to be a male. Because it was climbing the wall, this individual did not notice the two fighting at the top. It stopped and then immediately started retreating upon see-

ing them. Although the combatants were well into the "jumping" stage, it was chased, grabbed, and violently shaken, then thrown off the wall by one of the two, after which the original combat resumed. There was no head bobbing in this case.

The observed ritual might represent the introductory part of a conflict between two established (and possibly neighboring) males whereas wandering intruders might be encountered with a much more aggressive approach. This suggests that males of *E. caeruleocauda* might be territorial, a behavior observed in its congener *E. physicae* in New Guinea (Zwickel and Allison 1983. Can. J. Zool 64:752–755), but rarely observed in other skinks (Stamps 1983. *In* R. B. Huey et al [eds.], Lizard Ecology: Study of a Model Organism, Harvard Univ. Press, Cambridge, Massachusetts. 512 pp.). Specimens are deposited at the Ohio State Museum of Biological Diversity, Columbus, Ohio.

IGUANA DELICATISSIMA (Lesser Antillean Iguana). **ACTIVITY.** The genus *Iguana* is native to the Lesser Antilles, and both recognized species are known from the region. *Iguana iguana* is associated largely with the southern islands, although a natural introduction to the northern island of Anguilla has been documented (Censky et al. 1998. Nature 395:556). *Iguana delicatissima* has a more northerly distribution. Extant populations, some critically endangered, occur on the islands of Anguilla, St.-Martin/St. Maarten, St.-Barthélémy, St. Eustatius, Martinique, Dominica, Basse Terre and Grande Terre (Guadeloupe), and Désirade. Populations on St. Kitts, Nevis, Barbuda, Marie-Galante, Antigua, and Les Îles des Saintes have been extirpated (Malhotra and Thorpe. 1999. Reptiles & Amphibians of the Eastern Caribbean. Macmillan Educ. Ltd., London and Oxford, 134 pp.).

The critically endangered population of *Iguana delicatissima* on Anguilla has had to cope with an exceedingly xeric climate and periodic hurricanes. Since European colonization, additional pressures have been imposed in the form of habitat alteration and competition with, and predation by, introduced mammals. Recent estimates of population size suggest that fewer than 100 animals survive (Gerber 1997. Unpubl. rept., Fauna & Flora Internatl., Anguilla Natl. Trust, 22 pp.; E. J. Censky, pers. comm.). The recent arrival of *I. iguana* on Anguilla may represent a threat to the genetic integrity of the population. Day and Thorpe (1996. *In* Powell and Henderson [eds.], Contributions to West Indian Herpetology: A Tribute to Albert Schwartz, pp. 436–437. SSAR Contrib. Herpetol. Vol. 12. Ithaca, New York, 457 pp.) detected hybridization between *I. iguana* and *I. delicatissima* on Les Îles des Saintes through multivariate analysis of morphological characteristics and DNA testing. However, contact between the two species on Anguilla has not been documented.

Anguilla has an area of ca. 90 km^2. *Iguana delicatissima* utilizes only about 2 km^2 (3% of the total island area) along the northern coast of the island, from Little Bay west to the Brimigen Coast (Gerber, *op. cit.*). In the past, *I. delicatissima* had a much broader distribution along most of the northern coast, from Road Bay to Island Harbour (E. J. Censky, in litt., 26 July 2000). Despite the precarious state of the population, little is known about its natural history, although Gerber (*op. cit.*) noted habitat associations and diet. In an effort to begin documenting daily activities, focal animal observations were conducted over a three-week period in June 2000. We visited the entire current range of *I. delicatissima* on Anguilla; however, most observations occurred in the western portion, a ca. 100-m wide strip of land along the coast between Little and Limestone bays. This area consists of rocky limestone cliffs that rise to 25 m above sea level. Many of the iguanas that were observed used crevices and caves in the vertical faces of these cliffs as burrows. The dry thorn scrub vegetation above the cliffs rarely exceeded 3 m in height. Most of the area is relatively undisturbed by human activity, although some homes are present and the secluded beaches often attract tourists.

These iguanas are extremely secretive and sensitive to disturbance. Many Anguillians have never seen a wild iguana and the impression that this population had been extirpated was widespread as recently as the mid-1980s (E. J. Censky, pers. comm.). During >260 person-hours in the field, we spent ca. 47 hours observing animals. Some additional observations (all < 2 min in duration) consisted primarily of escape behavior in response to our presence and were not included in total observation time. Forty sightings were made of at least eleven different individuals (1 iguana/6.5 hr). Only five animals were observed for extended periods, most by a single observer using binoculars or a spotting scope to minimize the likelihood of altering behavior.

During the observation period, iguanas spent most of their time basking on rocks (86.0%) and considerably less time basking in trees (6.5%). Other activities included non-reproductive interactions (4.0%), courtship or mating (2.0%), roaming (1.8%), and feeding (0.2%). Additional time (0.4%) was spent in extended (> 2 min) responses to an observer. Variation was substantial among the five individuals observed for extended periods (Table 1). For example, some individuals were seen basking only in trees, whereas most were observed on rocks. We observed animals as early as 0700 h and as late as 1830 h, corresponding to about one hour after sunrise to sunset. No peaks in activity were observed; however, individuals were seen in trees primarily from 1100–1300 h.

Our observations are, at best, preliminary. Time spent feeding may have been underestimated in the context of general behavior, because individuals may have been more concerned about repro-

TABLE 1. Percent time spent per individual and total time spent per category: basking on rock (BR), basking in tree (BT), feeding (FF), non-reproductive interaction (NR), courtship and mating (CM), roaming (RR), and extended response to observer (RO).

duction than feeding during the mating season. Also, the overwhelming amount of time spent basking may merely reflect the fact that animals felt most secure and were most readily observed at those times.

Ellen J. Censky facilitated our work on Anguilla, helped in the field, and commented on an earlier draft of this note. Karim Hodge, Anguilla National Trust, helped us initially locate areas where animals were known to exist. Cleophis Gumbs kindly allowed us access to his property. Fieldwork was supported by Grant No. DBI-9732257 awarded by the National Science Foundation to RP.

KENTROPYX PAULENSIS (NCN)**. REPRODUCTION.** The terrestrial teiid lizard *Kentropyx paulensis* occurs in open habitat formations of central and southeastern Brazil (Gallagher and Dixon 1980. Copeia 1980:616–620). Data on natural history of species of the *K. paulensis* Group (*K. paulensis*, *K. vanzoi*, and *K. viridistriga*) are scarce. Here we describe reproductive information from five gravid female *K. paulensis* collected in a protected area of cerrado (savanna-like formation; 22°12'30"S, 47°54'45"W, 760 m elev.) at Itirapina Ecological Station (IES), municipality of Brotas, São Paulo State, southeastern Brazil. Three of the females laid eggs in the laboratory after collection. The first female (Zuec 02483; SVL = 70.0 mm; tail length = 137.8; mass = 10.5 g), collected on 27 August 1999, laid four white calcareous shelled eggs (15.2 x 8.8 mm, 15.3 x 8.8 mm, 14.5 x 9.8 mm, and 9.4 x 8.7 mm) on 1 September 1999; the total mass of the four eggs was 2.6 g (Relative Clutch Mass [RCM] = 0.25). The second female (SVL = 73.0 mm; tail length = 130.0; mass = 12.4 g), collected on 13 March 2000, laid five eggs on 17 March 2000; the total mass of the five eggs was 3.5 g (RCM = 0.28). The third female (SVL = 63.8 mm; tail length = 124.0 mm; mass = 9.0 g), collected on 13 February 2001, laid four eggs between 28 February and 1 March 2001. Afterwards the latter two females were marked and released in the field. Two additional females (Zuec 02485 and 02486; SVL = 71.3 and 73.0 mm; tail length = 123.0 and 139.0 mm; mass = 10.0 and 10.5 g; respectively) collected on 16 March 2000 and 17 February 2001 respectively, were preserved. They had three and five vitellogenic ovarian follicles respectively. Our data indicate that females of *K. paulensis* lay few (3–5) but large (RCM = 0.25–0.28) eggs. Teiid lizards generally have relatively low RCMs (0.11–0.21) which may be related to their widely foraging mode (Vitt and Price 1982. Herpetologica 38:237–255). The RCM for other species of the genus *Kentropyx* ranges from 0.15 to 0.22 (Vitt et al. 1995. Can. J. Zool. 73:691–703). The comparatively high RCMs we found for *K. paulensis* are among the highest within the Teiidae and the genus *Kentropyx*, which lead us to hypothesize that this species may have lower foraging intensity than other teiids.

The voucher specimens of *K. paulensis* cited above are deposited in the Museu de História Natural, Universidade Estadual de Campinas (ZUEC). D. Zanchetta and the staff of Instituto Florestal allowed and facilitated our fieldwork at IES. FAPESP provided grants to LAA (99/09125-1) and RJS (99/05664-5), and CNPq to MCK (146442/1999-7). We thank P. R. Manzani for laboratory assistance; V. R. Ariedi-Jr., V. Bonato, C. A. Brasileiro, C. Monteiro and F. Spina for field assistance; C. F. D. Rocha and M. Martins for suggestions. This is publication number 7 of the project Ecology of the Cerrados of Itirapina.

LIOLAEMUS PETROPHILUS (NCN). **SAUROPHAGY**. *Liolaemus petrophilus* is a tropidurid lizard found in the central massif of northern Patagonia (Chubut and Rio Negro Provinces), in Argentina. Data concerning biology and ecology of this species are scarce and diet of this species is unknown. Here we report an observation of interspecific saurophagy by an adult male *L. petrophilus* on a hatchling *L. bibroni*. On 29 January 2000, during the course of a herpetological trip carried out in central Rio Negro Province, we collected by hand from a small crevice situated on a rocky outcrop, an adult male L. *petrophilus* (FML 09145, SVL 84.5 mm, TL 224.0 mm, weight 20.35 g). We hand-captured the lizard and as we sought a more secure hold, the head of another lizard protruded from its mouth. We grasped the head and pulled out a complete, dead hatchling *L. bibroni* (FML 02170, SVL 23.6 mm, tail broken, weight 0.33 g). The stomach of the *L. petrophilus* was subsequently examined and found to be empty. Previous saurophagous behavior in *Liolaemus* lizards of Argentina has been documented under natural conditions for *L. koslowskyi* in northern La Rioja Province (Avila and Belver 2000. Herpetol. Rev. 31:174). *Liolaemus petrophilus* and *L. bibroni* are common and widespread in the Patagonian steppe and occasionally share similar microhabitats, such as rocky outcrops with spiny bushes. The frequency of predation on hatchlings of *L. bibroni* by adult *L. petrophilus* may thus be potentially common in this region.

Lizard identifications were verified by Fernando Lobo and specimens were deposited in the Herpetological Collection of the Instituto de Herpetología, Fundación Miguel Lillo, San Miguel de Tucumán, Tucumán, República Argentina (FML).

MABUYA BISTRIATA (NCN) **DIET.** *Mabuya bistriata* is a diurnal, forest-dwelling species that occurs on tree trunks, large limbs, and leaf litter; it feeds on a variety of invertebrates as well as vertebrates (Vitt and Blackburn 1991. Copeia 1991:916–927). Eco-

TABLE 1. Diet of 27 *Mabuya bistriata* from Silvânia, Brazil: (f) represents absolute frequency of each prey taxon in the sample; (f%) is relative frequency of each prey taxon; (C) is constancy or total number of stomachs in which each prey taxon was found; and (C%) is percentage of the total number of stomachs in which each prey taxon was found.

logical data on the scincid genus *Mabuya* in the cerrado are scarce, other than a few data for *M. frenata* (Vitt 1991. J. Herpetol. 25:79–90); Vrcibradic and Rocha 1998. J. Herpetol. 32:229–237). We examined the stomach contents of 27 *M. bistriata* collected September 1997 to August of 1998, from the cerrado at Estação Florestal de Experimentação do IBAMA, Silvânia municipality, State of Goiás, Brazil (16°39'26"S, 48°16'16"W). Table 1 summarizes the data. We found some plant material in the stomachs of 5 lizards (18.5%), but we considered it to be of incidental ingestion. We also found nematodes infecting 7 (25%) of the lizards. Orthopterans, ants, termites and beetles dominated the diet numerically, with orthopterans being the most numerous taxon in the diet of *M. bistriata*.

We thank A. P. Peña, S. L. Dutra, B. B. Santos, and L. G. Oliveira for help in the laboratory and with identification of animals; J. A. F. D. Filho, L. M. Bini, E. F. Júnior, C. M. Vieira, A. T. A. Jácomo, L. Silveira, D. Brandão, C. Hoffmann, and D. Blamires for help with data processing and statistics. RPB and RFJ are grateful to CNPq for fellowships. MICROLOPHUS ALBEMARLENSIS (Galapagos Lava Lizard). **CANNIBALISM**. Hamilton's Rule (Hamilton 1972. Ann. Rev. Ecol. Syst. 3:193–232) predicts that cannibalism should occur when the individuals involved are not likely to be closely related. On small islands, cannibalism may be selected against due to increased relatedness of individuals. Islote Punta Bowditch Norte is a small islet (2.9 ha, 0°31'57.7"S, 90°31'1.7"W) near the center of the Galapagos Archipelago, Ecuador. On 4 February 1994, while conducting a census of lizards, we observed a female lava lizard, *Microlophus albemarlensis*, eating a juvenile. The female was eating the juvenile head-first, with the back legs and tail of the juvenile protruding from the female's mouth. Our presence did not interrupt the interaction and neither lizard was captured or collected. The female moved away and out of sight within two minutes, before completing ingestion of the juvenile. The female appeared to be normal size for this island (ca. 73 mm SVL) and the juvenile appeared to be a young of the year (ca. 40 mm SVL). The only other lizards on this island are the marine iguana (*Amblyrhynchus cristatus*) and the gecko (*Phyllodactylus galapagoensis*), neither of which are in the size range of the juvenile. Thus, the identification of the juvenile is certain. Stebbins et al. (1967. Ecology 48:839–851) collected the tail of a juvenile *M. albemarlensis* from the stomach of a male *M. albemarlensis* on the large island of Santa Cruz, but because of tail autonomy it is not clear if this was cannibalism or scavenging. Werner (1978. Z. Tierpsych. 47:337–395) reported cannibalism in *M. delanonis* on the large island Española, and Carpenter (1970. Herpetologica 26:377–386) reported cannibalism in *M. habelii* on the large island of Marchena. Our observation is noteworthy because it is the first record of cannibalism in *M. albemarlensis*, and because the cannibalism occurred on such a small island.

PHELSUMA MADAGASCARIENSIS KOCHI (Madagascar Day Gecko). **DIET**. *Phelsuma* are conspicuous diurnal gekkonids which comprise more than 20 species living on Madagascar. During a long-term fieldwork project in the Ankarafantsika Reserve, western Madagascar (Ampijoroa Forest Station, 16°20'S, 46°47'E, altitude ca. 70 m above sea level) one of us (GG) had the opportunity to observe the behavior of the large species *P. madagascariensis kochi* (up to 305 mm total length; Glaw and Vences 1994. Fieldguide to the Amphibians and Reptiles of Madagascar, second edition. Serpents T, Köln. 480 pp.). Although mostly diurnal,

FIG. 1. *Phelsuma madagascariensis kochi* capturing a *Hemidactylus* specimen (probably *H. frenatus*) at Ampijoroa forestry station.

these geckos showed regular nocturnal activity, especially when living in or close to human settlements with artificial light at night. On a white wall, specimens were observed regularly at night hunting other geckos (*Hemidactylus* sp.). Under a roof constructed by leaves of Baobao (*Raphia farinifera*) and Satrana (*Hyphaene shatan*) palms at Ampijoroa forestry station, the otherwise nocturnal *Hemidactylus* were sometimes seen during the day, and then were also actively hunted by *Phelsuma*. One such act of predation was photographed (Fig. 1). *Phelsuma* may be one of the most important predators of *Hemidactylus* under such conditions at Ampjoroa.

Submitted by **GERARDO GARCÍA**, Durrell Institute of Conservation and Ecology, University of Kent, Canterbury, Kent CT2 7NS, U.K. (e-mail: gerardo.garcia@wanadoo.fr, and **MIGUEL VENCES**, Laboratoire des Reptiles et Amphibiens, Muséum National d'Histoire Naturelle, 25 rue Cuvier, 75005 Paris, France (e-mail: m.vences@t-online.de).

TROPIDURUS NANUZAE (NCN). **DEATH FEIGNING**. The saxicolous lizard *Tropidurus nanuzae* is a small tropidurid restricted to parts of the Espinhaço Mountain Range, Brazil, at altitudes above 1200 m (Rodrigues 1988. *In* Heyer and Vanzolini [eds.], Proceedings of a Workshop on Neotropical Distribution Patterns, pp. 305–315. Academia Brasileira de Ciências, Rio de Janeiro). Present knowledge of the natural history of this species is scarce. Here we describe a new antipredator behavior for this species.

From 9 to 12 July 2001, during field work at the Serra do Cipó (19°0'S, 43°40'W), Minas Gerais, Brazil, we observed that, during manipulation, five young and one adult *T. nanuzae* extended their limbs upward and closed their eyelids, remaining motionless for several seconds while laying belly-up (for one individual, we registered a duration of 50 sec for such behavior). Some young also feigned death when placed inside plastic bags to be weighed.

Death feigning or thanatosis is a relatively widespread defensive tactic among lizards, being observed in species of different families (Greene 1988. *In* Gans and Huey [eds.], Biology of the Reptilia, vol. 16. Allan R. Liss, Inc., New York. 672 pp.). Death feigning has been previously observed in another tropidurid, *Liolaemus lutzae* (Rocha 1993. Ciência e Cultura 45:116–122), and is here reported for a second species of this family.

We thank Davor Vrcibradic for offering helpful suggestions on a previous version of this manuscript and IBAMA for providing logistical support. One of us (CABG) benefited from a graduate fellowship from Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES).

examined the stomach contents of 32 specimens collected from September 1997 to August of 1998 from the cerrado and in a gallery forest, at the Estação Florestal de Experimentação (16°39'26"S, 48°16'16"W), Silvânia municipality, State of Goiás, Brazil. Table 1 summarizes the data. The diet of *T. torquatus* was similar in both habitats: Coleoptera, Formicidae, and Isoptera were the dominant food items. The niche breadth (*sensu* Pianka 1986. Ecology and Natural History of Desert Lizards. Princeton University Press, Princeton, New Jersey. 208 pp.) was also very similar (cerrado = 2.92; gallery forest = 3.19).

(Refuge Headquaters: 36°40'19"N, 75°54'55"W) in Virginia Beach, Virginia, USA, from September 1995 through May 1998. This study was undertaken as part of an extensive ecological investigation of heretofore unstudied populations of the eastern cottonmouth in southeastern Virginia in order to compare the ecology of this species in two very different marsh habitats: (1) a 1200 ha relatively undisturbed marsh containing mostly late successional vegetation (natural marsh) and (2) a 1900 ha actively managed series of waterfowl impoundments kept at a low seral stage via burning, plowing, dredging activities, and seasonal manipulations of water depth (anthropogenic marsh) (Cross 1998. Ph.D. dissertation. Old Dominion University, Norfolk. 164 pp.).

Stomach contents were obtained from 56 adult cottonmouths captured as part of a mark-recapture study; additionally, three snakes found dead on the Refuge were dissected to obtain stomach contents. After cottonmouths were captured and marked by scale-clipping, snakes were secured by placing their head and ca. 10 cm of their neck into an appropriately sized clear acrylic tube. Stomach contents were gently palped by finger pressure to within a few centimeters of the head (see Fitch 1987. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 143–164. McGraw-Hill, New York.), after which the snake was placed into a squeeze box (Cross 2000. Herpetol. Rev. 31:34) where the food was regurgitated. Items were collected, bagged, sealed, labeled for future identification, and frozen. Contents were later weighed, measured, and identified in the laboratory.

A majority (66%) of the stomachs examined contained food items or liquid material; 30% of examined stomachs were empty. Green frogs (*Rana clamitans*) were the most common food item, followed closely by sunfish (*Lepomis* spp.) and southern leopard frogs (*R. utricularia*). Reptilian prey items were found in three stomachs; one contained a northern water snake (*Nerodia sipedon*) and two contained turtles (evidenced from the shape of the food bolus; they were not palped out of stomachs due to the possibility of injuring the snakes). Only one stomach contained mammalian remains (*Microtus* sp.). Twenty stomachs contained liquid with a slurry of nearly fully digested, and hence unidentifiable, prey. Twenty-two snakes contained non-food items, including rocks, sand, dirt, vegetation, and wood material (Table 1). A large male snake was seen in a slow and presumably predatory approach of a plover (*Charadrius* spp.), but the bird escaped before a strike was made. A large female cottonmouth was seen swallowing a large *Rana clamitans*. The frog, which was being swallowed by the posterior end first, was still alive and delivered a loud distress call.

I thank A. H. Savitzky for helpful suggestions and support throughout this investigation. I thank J. B. Gallegos, J. Stasko, F. G. James, and all of the other BBNWR staff that assisted in this project. Partial funding for this research was provided by a grant from the U.S. Fish and Wildlife Service, Back Bay National Wildlife Refuge. I thank D. Bradford for making useful comments on earlier versions of this manuscript. *NOTICE*: The research described here was developed by the author prior to his employment with the U.S. Environmental Protection Agency's Office of Research and Development. The manuscript has been subjected to administrative review but the conclusions drawn are solely those of the author. Mention of trade names or commercial products does not constitute endorsement or recommendation by EPA for use.

CROTALUS VIRIDIS OREGANUS (Northern Pacific Rattlesnake). **COSTS OF FEEDING**. In cases where locomotion is a critical aspect of predator avoidance and the ingestion of prey items reduces locomotor performance, the eating of a large meal should reduce the ability to escape from a predator. Reduction in snake locomotor capacity after the ingestion of a large meal has been documented in juvenile garter snakes (*Thamnophis* sp.)(Garland and Arnold 1983. Copeia 1983:1092–1096; Ford and Shuttlesworth 1986. Copeia 1986:999–1001). In these studies, the impact of prey items up to 50% of the snakes' body mass was examined. In crotalines, the ability to consume prey up to 156% of the snakes' weight has been documented (Greene 1983. Amer. Zool. 23:431–441). However, only a single anecdotal account suggests how locomotory capabilities of these vipers may be impacted by the ingestion of such large prey items. Fitch reported that the movements of a young *C. v. oreganus* were so hampered after consuming a pocket mouse (*Perognathus*) that it was unable to reach its usual shelter before dying of exposure to sunshine (1949. Amer. Midl. Nat. 41:513–579).

Here we report on an observation of a juvenile female *C. v. oreganus* (272.5 mm SVL, 296.5 mm TL, 11.91 g mass with prey item removed) that was found at 1300 h on 6 May 2000 at Stebbins Cold Canyon Reserve, Solano Co., California, USA. Although the snake was found alive, it had recently sustained a presumably lethal wound after the consumption of a large meal. The wound extended the length of 12 ventral scales (16.1 mm, ca. 6% of TL) and the height of eight dorsal scale rows (10.1 mm, ca. 25% circumference), and it included the loss of a section of skin, ribs, and stomach. The remaining hole revealed the left hind limb and a portion of the ventral surface of a male *Sceloporus occidentalis* (66.9 mm SVL, 153.7 mm TL, 9.04 g). The relative prey mass of this meal is 0.76. The *S. occidentalis* was swallowed headfirst and exhibited only a minor degree of decomposition.

Based upon the severity of the wound and the removal of the large section of tissue, we infer that the wound did not result from prey capture but from a predatory attack, possibly due to the reduced escape ability of the engorged *C. viridis*. Mobility may also have been reduced by weather conditions. The temperature was ca. 15°C with a light rain falling. However, a second juvenile *C. v. oreganus*, found ca. 200 m upstream, was capable of reaching a nearby shelter after being disturbed. As a result, we suggest that the greatest contributing factor to a reduction in escape ability, and therefore an increase in predation risk, was the ingestion of the large prey item.

The specimen was collected under California Department of Fish and Game Permit 803027-01 to GBP and deposited at the University of California, Davis Museum of Zoology (UCDMZ 12277). We thank H. Bradley Shaffer for support and helpful comments on this note.

LEIOHETERODON MADAGASCARIENSIS (Madagascar Menarana Snake). **DIET**. The diet of captive *Leioheterodon madagascariensis* (Colubridae) includes fish, frogs, reptiles, birds, and rodents (Campbell and Murphy 1977. J. Herpetol. 11:228–230; Conant 1938. Zoologica 23:389–393; Dathe and Dedekind 1996. Zool. Garten 66:69–76; Groves and Groves 1978. Herpetol. Rev. 9:19–20; Henkel and Schmidt 1995. Amphibien und Reptilien Madagaskars der Maskarenen, Seychellen und Komoren. Eugen Ulmer, Stuttgart. 311 pp.). However, only frogs are reported as prey of wild individuals (Preston-Mafham 1991. Madagascar, A Natural History. Facts On File, Oxford. 224 pp.).

During a field study at the Jardin Botanique A of Ampijoroa, Madagascar, we recovered stomach contents from six individuals of *L. madagascariensis* by forced-regurgitation. All snakes were collected while they were crawling on trails in the dry forest. The stomach contents consisted of eggs of a lizard, *Oplurus cuvieri cuvieri* (Opluridae), partially digested adult rodents (Nesomyinae), and tufted feathers of an adult, unidentified bird (Table 1). The eggs were identified based on their size, shape, coloration, and roughness of the shells (Randriamahazo, unpubl. data).

This study was financially supported by Grants-in-Aid under the Monbusho International Scientific Research Program (Field Research, nos. 06041093 and 11691183). We thank Shigeki Asai for collecting a snake and the staff of Parc Botanique et Zoologique de Tsimbazaza for their assistance in the field study.

TABLE 1. Stomach contents of *Leioheterodon madagascariensis* collected in Ampijoroa, northwestern Madagascar.

Collection Time	Collection Date	SVL (mm)	Body Mass (g)	Stomach Contents

Submitted by **AKIRA MORI** and **HERILALA JEAN AIMÉ RODOLPH RANDRIAMAHAZO**, Department of Zoology, Graduate School of Science, Kyoto University, Sakyo, Kyoto, 606-8502 Japan; e-mail [AM]: gappa@zoo.zool.kyoto-u.ac.jp.

LEIOHETERODON MODESTUS (Madagascar Brown Snake). **DIET**. On 2 November 1999, at 0815 h, an adult male *Leioheterodon modestus* (Colubridae) was captured crawling out of a burrow on an ant mound in the dry forest at the Jardin Botanique A of Ampijoroa, Madagascar. The snake (886 mm SVL, 347 g mass) was force-regurgitated, and a snake egg was recovered from its stomach. Dissection of the egg revealed a fully developed embryo of the colubrid snake, *Mimophis mahfalensis* (156 mm SVL, 1.3 g mass).

Blanc (1984. *In* Jolly et al. [eds.], *In* Madagascar, pp. 105–114. Pergamon Press, Oxford) noted that *L. modestus* hunts lizards. Preston-Mafham (1991. Madagascar, A Natural History. Facts On File, Oxford. 224 pp.) observed this species foraging on the forest floor and detecting a frog hidden in the sand. The egg of *M. mahfalensis* was obviously ingested in its oviposition site, indicating that the snake employed a widely foraging tactic.

This study was financially supported by Grants-in-Aid under the Monbusho International Scientific Research Program (Field Research, no. 11691183). I thank the staff of Parc Botanique et Zoologique de Tsimbazaza for their assistance in this field study.

MASTICOPHIS FLAGELLUM FLAGELLUM (Eastern Coachwhip). **DIET**. On 1 June 2000 at 1430 h (air temperature = 30°C), as one of us (DJS) approached a drift fence in longleaf pine (*Pinus palustris*)-turkey oak (*Quercus laevis*) sandhill on the Fort Stewart Military Installation, Bryan County, Georgia, USA, a male *Masticophis f. flagellum* (914 mm SVL; 1226 mm TL) crawled rapidly away from the fence. A few seconds later the snake paused ca. 15 m from the fence; a moderate-sized lump, presumed to be a prey item was evident in the throat of the snake. When captured, the snake immediately disgorged the item that was an adult male six-lined racerunner (*Cnemidophorus sexlineatus*; 69 mm SVL). The snake weighed 130 g after regurgitating the lizard. The racerunner, examined immediately after being disgorged, was putrid and had ca. 20 live red imported fire ants (*Solenopsis invicta*) clinging to its body near a hole (8 x 6 mm) which extended into its neck from the dorsum. A pitfall trap close to where the snake was first observed contained 1 live and 1 dead adult *C. sexlineatus*, as well as fire ants.

These observations indicate that this *C. sexlineatus* was already dead and had been partly consumed by fire ants before being eaten by the coachwhip. We believe it is likely that the snake took the dead lizard from a pitfall trap along the drift fence. Although western subspecies of *M. flagellum* have been reported to feed on carrion, including a dead snake (Small et al. 1994. Herpetol. Rev. 25:28) and a dead bird (Cowles 1946. Herpetologica 3:121–122), this is the first report of carrion feeding by *M. f. flagellum*, as far as we are aware.

Submitted by **DIRK J. STEVENSON** and **KAREN J. DYER**, Fort Stewart Fish and Wildlife Branch, Directorate of Public Works, 1113 Frank Cochran Drive, Fort Stewart, Georgia, 31314-4940, USA; e-mail (DJS): stevensond@emh5.stewart.army.mil.

MICRURUS FULVIUS (Eastern Coral Snake). **PREY**. *Micrurus fulvius* has been documented to feed on a variety of vertebrates including mammals, anurans, amphisbaenids, anguids, iguanids, scincids, teiids, leptotyphlopids, colubrids, viperids, and other elap-

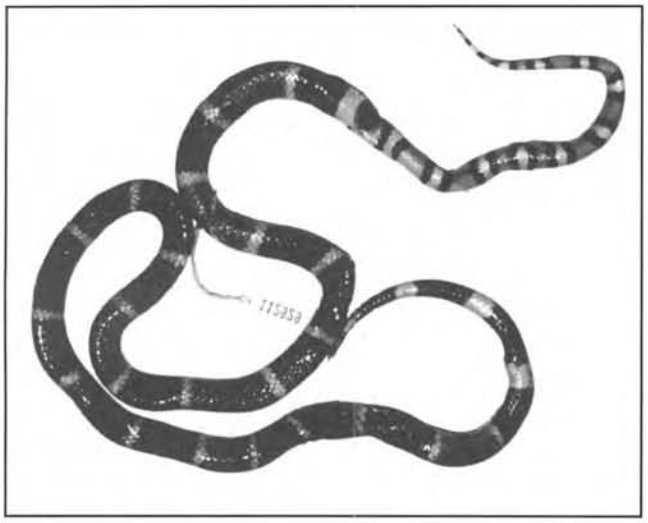

FIG. 1. *Micrurus fulvius* feeding on *Lampropeltis triangulum elapsoides*, Gilchrist Co., Florida.

ids (Jackson and Franz 1981. Herpetologica 37:221–224; Greene 1984. Spec. Publ. Univ. Kansas Mus. Nat. Hist.10:147–162; Tennant et al. 1997. A Field Guide to the Snakes of Florida. Gulf Publ. Co., Houston, Texas. 272 pp.). Here we report a prey item not previously recorded.

On 4 April 1998, a neighborhood dog near Newberry, Gilchrist County, Florida, USA, killed an adult male *M. fulvius*. This snake was in the process of eating an adult scarlet kingsnake (*Lampropeltis triangulum elapsoides*)(Fig. 1). Both snakes were deposited in the Florida Museum of Natural History (UF 112929). This note demonstrates the predation of an ophiophagous, Batesian mimic (*L. t. elapsoides*) by its ophiophagous model (*M. fulvius*), as well as conservation implications associated with domestic carnivores.

We thank M. A. Nickerson for helpful suggestions on this note.

MORELIA AMETHISTINA (Scrub Python). **DIET**. *Morelia amethistina* is Australia's largest snake and feeds on a wide range of vertebrates, mainly birds (Loop 1995. Mem. Qld. Mus. 38[2]:504) and mammals (Shine and Slip 1990. Herpetologica 46:283–290.). Although it is reported that *M. amethistina* commonly feeds on large macropods, quantification of this aspect of their feeding ecology is rudimentary (Greer 1997. The Biology and Evolution of Australian Snakes. Surrey Beatty & Sons. NSW, 358 pp.).

On 30 March 2001, I was requested to remove a large *M. amethistina* which was in the process of constricting a wallaby at a residential property at Balgal Beach (19°01.540'S, 146°24.334'E), 50 km north of Townsville, northeast Queensland. The snake had already commenced ingestion of an adult female agile wallaby (*Macropus agilis*) when I arrived (Fig. 1). The wallaby was estimated to weigh 10 kg. Several days later, an adult female *M. agilis* of very similar dimensions was examined as a road kill and found to weigh 10.2 kg with a head/body length of 63 cm, which is typical for adult females of this taxon (Strahan 1995. The Mammals of Australia. Reed Books. Sydney, 756 pp.). The wallaby was attacked from the ground on the edge of a narrow path through dense, woody vegetation. The path is regularly used by *M. agilis* individuals when entering the property for feeding by the owner. The wallaby was attacked shortly before 1910 h and the property owner reported a violent struggle before the wallaby succumbed. This was corroborated by the presence of two large wounds in the anterior venter of the snake, the largest of which (4 cm x 3 cm) penetrated the snake's body cavity, exposing underlying structures, particularly the trachea (Fig. 2). The long and powerful fourth toe of the wallaby's right hind foot was covered in blood but exhibited no apparent injury and appeared to be responsible for the wounds inflicted on the snake.

Ingestion was completed at 2125 h with the snake apparently undisturbed at being watched by torch light and flash photographed at numerous intervals. The peculiar bulbous body shape of large macropods appeared to be responsible for most of the time that elapsed between initiation and completion of ingestion. The snake made rapid progress until it reached the wallaby's pelvic region. During ingestion of this portion of the carcass the snake took long pauses between attempts to draw more of the prey into its mouth and could be heard exhaling heavily through its protruding glottis. The snake appeared to be continually working its coils in an attempt to laterally compress the carcass at its widest diameter to facilitate swallowing.

At the request of the property owner, the snake was removed shortly after ingestion and returned to Townsville for further observations. The snake was placed in a 120 x 60 x 60 cm cage and maintained at ambient temperatures in a room of a brick house with an easterly aspect. Cage temperatures were recorded with a digital thermometer five times each day and night (between 0900 and 2400 h) during the digestive period. Mean diurnal temperature was 29.8°C (range 27.8–31.1°C) and mean nocturnal temperature 28.1°C (range 26.8–29.2°C).

Digestion of such a large prey item was rapid, with the snake passing large uric acid deposits on April 1, 3, and 4. A large stool was produced on the evening of April 5. By April 6, the snake's mid-body bulge was greatly reduced and it was decided to manually remove the snake from the cage for cleaning. The same evening, the remaining portion of the wallaby was regurgitated,

FIG. 1. Adult *Morelia amethistina* ingesting an adult female agile wallaby (*Macropus agilis*).

FIG. 2. Prey bolus in adult *M. amethistina* following ingestion of adult *Macropus agilis*. Note gaping wound in anterior venter of snake inflicted by claw of wallaby's large fourth toe.

possibly in response to handling. The regurgitation consisted of a 1.6 kg portion of rump and two femurs. Forty-eight hours later the snake was sexed, weighed, and its dimensions recorded: female, 3705 mm SVL, 625 mm tail, 260 mm mid-body girth, 13.5 kg, 95 mm head length along lower jaw, from tip of snout to posterior edge of quadratearticular projection, 64 mm head width at base of skull, 37 mm head width between eyes). Body length was determined by stretching the snake along a tape measure, head measurements were obtained with Vernier calipers, and sex was determined with a sexing probe.

Morelia amethistina is one of the world's largest snakes and macropods are the most abundant and readily available large prey resource throughout the snake's Australian range (Strahan 1995, *op. cit.*). Mark/recapture and radiotelemetric evidence (SF, research in progress) indicates that mature *M. amethistina* specifically target macropods (particularly *Macropus agilis* and red-legged pademelons, *Thylogale stigmatica*) and spend long periods of time waiting in ambush at localities frequented by these mammals.

The wounds inflicted on the snake in this report are very similar to those described for a 3.3 m *M. amethistina* that appeared to be specifically targeting Bennett's tree kangaroos (*Dendrolagus bennettianus*) near Cooktown, northeast Queensland (Martin 1995. Herpetol. Rev. 26:74–76). The snake in this report, in addition to the fresh wounds described, also displayed recently-healed scars in the same region of its neck. The presence of such wounds and scars may be a reliable indicator of recent predation on large macropods. Wounds and scars from biting inflicted during intraspecific male combat in this taxon are of a very different configuration, occurring dorsally at various places along the body and taking the form of clean cut, straight-edged parallel striations (pers. obs.).

Sincere thanks to D. Seabright for bringing the snake to my attention. Thanks also to J. Elliott, D. Frier, S. Patane, and D. Trembath for assistance with snake handling and data collection. D. Barton and R. W. Hansen commented on the manuscript. This work was conducted under permit number F1/000330/00/SAA from the Queensland Environment Protection Agency and James Cook University Ethics Approval Number A594-00.

Submitted by **SIMON FEARN**, School of Biological Sciences, James Cook University, Townsville, Queensland, Australia, 4811; e-mail: simon.fearn@jcu.edu.au.

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga). **MAXIMUM LENGTH.** Boundy (1995. Bull. Chicago Herpetol. Soc. 30:109–122) reports the maximum length of this subspecies as 530 mm TL based on a specimen originally reported by Gloyd (1955. Bull. Chicago Acad. Sci. 10:83–98). I have examined two specimens from the San Bernardino Valley, Cochise County, Arizona, USA, which exceed this length. A live male collected 27 July 1994 measured 578 mm TL (534 mm SVL) and a male collected 24 July 1995 (DOR) measured 588 mm TL (541 mm SVL). The former was marked (1F30491E4A) and released; the latter resides in the Arizona State University vertebrate collection (ASU 30622).

Submitted by **ANDREW T. HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA; e-mail: holycow@asu.edu.

THAMNOPHIS RADIX (Plains Garter Snake). **BROOD SIZE.** Brood sizes for *Thamnophis radix* show much geographical variation (Fitch 1985. Misc. Publ. Univ. Kansas Mus. Nat. Hist. 76:1–76). While brood sizes can range up to 60 (Fitch, *op. cit.*; Collins 1993. Amphibians and Reptiles in Kansas. Univ. Kansas Mus. Nat. Hist., Lawerence, Kansas, 397 pp.), the brood sizes reported for Colorado have fallen far short of this. Hammerson (1999. Amphibians and Reptiles in Colorado, Second Edition. University Press of Colorado, Niwot, Colorado, 480 pp.) observed brood sizes in Colorado of 16–21 (N = 9), with a mean of 16. Rossman et al. (1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman) reported a range of 5–20 (N = 8) for Colorado, and a brood of 20 was recorded by Ellis and Henderson (1913. Univ. Colorado Studies 10:39–129). Other records include brood sizes of 7, 9, 14, 20, and 21 (Hammerson, *op. cit.*).

On 23 July 2000 we captured a gravid 58 cm SVL female *T. radix* near Spring Ck in Fort Collins, Colorado, USA. By the morning of 24 July she had given birth to 32 young. The time of year for appearance of young appeared typical (Hammerson, *op. cit.*), but the brood size was substantially (50%) in excess of the maximal brood size previously reported for Colorado.

Submitted by **RICHARD M. ENGEMAN**, National Wildlife Research Center, 4101 LaPorte Avenue, Fort Collins, Colorado 80521-2154, USA, **ISABEL M. ENGEMAN** and **ALEXANDER N. ENGEMAN**, 3902 Carrick Road, Fort Collins, Colorado 80525, USA.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother 2000. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*. SSAR Herpetol. Circ. 29:1–82; for Mexico as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*. Herpetol. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*; available from the SSAR Publications Secretary) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: **Alan M. Richmond** (USA & Canadian records only), Biology Department, Morrill IV South, 611 North Pleasant Street, University of Massachusetts, Amherst, Massachusetts 01003-9297, USA; **Jerry D. Johnson** (Mexico and Central America, including the Caribbean islands), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA; **Hidetoshi Ota** (all Old World records), Tropical Biosphere Research Center, University of the Ryukyus, 1 Senbaru, Nishihara-cho, Okinawa 903-01, Japan; or **Gustavo J. Scrocchi** (South American records), Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina. Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Submissions by e-mail are encouraged where possible**. Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Marques, O. A. V., and G. Puorto. 1996. Geographic Distribution. *Chironius laevicollis*. Herpetol. Rev. 27:212.

CAUDATA

DESMOGNATHUS WRIGHTI (Pigmy Salamander). USA: NORTH CAROLINA: Jackson Co: Panthertown Valley, a 2700-hectare management 5 area within the Nantahala National Forest Highlands Ranger District in a *Rhododendron maximum* thicket along an unnamed headwater tributary of Greenland Creek, ca. 1280 m (35°8.42'N, 82°59.81'W). 12 October 1997. Joseph Bernardo and Pamela T. Plotkin. Frostburg State University (JB 9712), NCSM 62157–158. All verified by Alvin Braswell. Extends verified range to just north of the Tennessee Valley Divide along the Southern Blue Ridge, ca 19.7 km SSE Rough Butt Bald (Great Balsam Mountains), which is north of Tuckasegee River and Tanasee Gap, and 37.2 km SSW Blackrock Mountain (Plott Balsam Mountains), which is also north of Tuckasegee River. Within Cowee Mountains, this locality extends range SE of the low elevation valley (ca. 710 m) that contains Savannah and Watauga Creeks. SE of the West Fork of Tuckasegee River (750–800 m), and 37.8 km SE of the Cowee Bald locality reported by Bruce (J. Herpetol. 11:244–246).

Submitted by **JOSEPH BERNARDO**, Department of Biology, Frostburg State University, 101 Braddock Road, Frostburg, Maryland 21532, USA; e-mail: jbernardo@frostburg.edu.

NECTURUS MACULOSUS (Common Mudpuppy). USA: IOWA: Scott Co: Bettendorf, Pleasant Valley Township, foot of 4th Street bridge. 20 April 1957. Bob Alex. HDW-NIU 1830; Davenport, Davenport Township. 16 October 1965. Gladys McGrath. HDW-NIU 1919. Verified by Christine Chandler. (Christiansen 1998, Proc. Iowa Acad. Sci. 105[3]:109–114) records the last specimen having been taken before 1950 in eastern Iowa, whereas, these records give indications of isolated populations still present in the Mississippi River. Christiansen (*op. cit.*) noted that populations have declined or have been extirpated from downstream regions in Iowa. This also holds true for southwestern Wisconsin where a commercial fisherman, Jim Hagensick, has informed me that "this species was taken in set lines during the winter and early spring months, although for the past few years only one or two specimens are taken each year." The floods of 1995 and 2001 have drastically altered the flow of the Mississippi, as have locks and dams, which have added to the siltation problem.

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

NECTURUS MACULOSUS (Common Mudpuppy). USA: ILLINOIS: Kane Co: Aurora, Fox River. 12 May 1952. J. D. Barton, Jr. HDW-NIU 766. Verified by Phil Senter. Validates a previous record cited without a voucher specimen by Smith (1961, Bull. Illiinois Nat. Hist. Surv. 28:1–298) and Phillips et al. (1999, Illinois Nat. Hist. Surv. Manual 8:1–282).

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, Dekalb, Illinois 60115, USA.

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). USA: MICHIGAN: Charlevoix Co: Garden Island (N45°47.90' W85°30.39'), under a log on West Side Trail near the Native American Cemetery. 15 May 2001. Kenneth D. Bowen. Verified by Nancy E. Seefelt. Central Michigan University Museum of Culture and Natural History (CMU A-1610). First verified record of this animal for Garden Island.

Submitted by **KENNETH D. BOWEN** and **JAMES C. GILLINGHAM**, Department of Biology, Central Michigan University, Mt. Pleasant, Michigan 48859, USA.

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). USA: LOUISIANA: Cameron Parish: Lowry area; 4 mi S jct. Hwy 14 and Hwy 3056, Lacassine National Wildlife Refuge. 25 June 2001. Elizabeth Johnson and Bradley Bordelon. Seale Museum of Louisiana, McNeese State University (SML 9327–9). Verified by Steve Shively. First Parish record. This record extends the State distribution south from Calcasieu Parish and west from Vermilion

Parish as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

ANURA

AMOLOPS SPINAPECTORALIS (Spinyback Torrent Frog). VIETNAM: QUANG NAM PROVINCE: Ngoc Linh Mountain Range, Tra My District, 980–1020 m elev. (15°11'41"N, 108°02'25"E). Nguyen Quang Truong. Verified by Nikolai Orlov. American Museum of Natural History (AMNH) A-163707. First provincial record for Quang Nam (Inger et al. 1999. Fieldiana Zool. 92, pp.12–13, Fig. 4).

ANODONTHYLA BOULENGERI. CORRECTION OF LOCALITY RECORD: MADAGASCAR: MAROJEJY. Verified by Annemarie Ohler. Marojezy (current spelling: Marojejy) in northeastern Madagascar was the northernmost record of this species (Blommers-Schlösser and Blanc 1991. Amphibiens (première partie). Faune de Madagascar 75[1]:1–379) but has not been verified in recent surveys (pers. obs., and Raselimanana et al. 2000. Fieldiana Zoology 97:157–174). The locality records of Blommers-Schlösser and Blanc (*op. cit.*) were almost exclusively based on the collections of the Muséum national d'Histoire naturelle, Paris (MNHN) and the Zoölogisch Museum Amsterdam, which we have recently revised. Two vouchers originating from Marojejy and catalogued as *Anodonthyla boulengeri* were found, namely MNHN 1972.688 ("Marojezy 1300 m," collected on 2 December 1972) and MNHN 1975.2309 ("Marojezy 1700 m," collected on 1 December 1972). Both are juveniles of 10.4 and 12.0 mm snout–vent length which cannot be reliably determined at species level. However, they have a fifth toe which is only slightly shorter (MNHN 1972.688) or even longer (MNHN 1975.2309) than the third toe, while in *A. boulengeri* the fifth toe is always much shorter than the third toe. Therefore, these specimens clearly are not *A. boulengeri*. All species of *Anodonthyla* are characterized by a reduced first finger without an evident terminal disc, a state already recognizable in juveniles (e.g., *A. rouxae*, MNHN 1973.634, SVL 10.5 mm). The two Marojejy vouchers do have a normal-sized first toe, and we therefore refer them to the genus *Platypelis*.

The next northernmost record (and the only other record in the northeastern biogeographic region) of the genus *Anodonthyla* is Anjanaharibe-Sud (Raxworthy et al. 1998. Fieldiana Zoology, n.s. 90:79–92). However, our re-examination of vouchers from this locality in the Museo Regionale di Scienze Naturali, Torino, showed that they belong to undescribed cophyline species which are likely to be assigned to the genus *Platypelis*. Similarly, the only voucher from Anjanaharibe in the Museum of Zoology of the University of Michigan (UMMZ 214153) has been re-determined by S.-H. Wu as undescribed species of *Platypelis* (G. Schneider, pers. comm., September 2001). Further surveys at several sites in northeastern Madagascar (e.g., Ambolokopatrika, Besariaka, Tsararano) carried out by one of us (FA) did not yield specimens of *Anodonthyla*. This also includes sites in the Masoala reserve (e.g., Ambatoledama, Beanjada, Ilampy, Menamalona), although *A. boulengeri* was observed at Nosy Mangabe Island, close to Masoala and to the northern limit of the eastern region. We therefore propose to consider the Marojejy record for *A. boulengeri* as erroneous and the Anjanaharibe record as in need of confirmation. As a conclusion, the species and the whole genus is currently not known from the northern biogeographic regions, confirming that its centers of diversity and endemism are in the southern part of Madagascar.

HYLA CALCARATA (Rana de Espolones). VENEZUELA: ESTADO DELTA AMACURO: Caño Guaramo, tributary of Caño Ibaruma, lower Delta del Orinoco. 23–28 February 1995. J. C. Señaris. Museo de Historia Natural La Salle, Caracas (MHNLS 13056, 13106). Verified by César Molina. In Venezuela this species has been reported to the upper Orinoco River in the Colombian-Venezuelan border (Duellman 1973. Copeia 1973:515–533) and to middle Caura River Basin in Bolívar State (Molina 2001. Herpetol. Rev. 32:114). Donnelly and Myers (1991. Am. Mus. Novitates 3017:1–54) reported this species from Cerro Guaiquinima, and Barrio (1998, Acta Biol. Venez. 18[2]:1–93) observed the species in Río Aguas Negras, south Cerro Santa Rosa, in Bolívar State. The specimens reported here represent the first state record and extend the known range for this species ca. 300 km to the NE from the nearest locality, Río Aguas Negras, Bolívar state (Barrio, *op. cit.*). This finding corroborates the occurrence of Upper Amazonian herpetofauna in the delta of the Orinoco River, and supports the hypothesis that this region acts as an Amazonian corridor to NE Venezuela and Trinidad.

Submitted by **JOSEFA CELSA SEÑARIS**, Museo de Historia Natural La Salle, Caracas (e-mail: celsas@mixmail.com), and **CÉSAR LUIS BARRIO**, Fundación AndígenA, Apartado Postal 210, Mérida 5101-A, Venezuela (e-mail: cesarlba@yahoo.com).

HYLORINA SYLVATICA. ARGENTINA: NEUQUÉN: DEPARTAMENTO LÁCAR: Lanín National Park, Yuco, N side of Lácar Lake, 40°10'06"S, 71° 31'37"W, ca. 700 m elev., 9 January 2000. Marcelo L. Ochoa. Fundación Miguel Lillo, Tucumán, Argentina (FML 10373, color slide). Adult. Verified by N. G. Basso. Lanín National Park, Escondido Lake, 40°14'S, 71°33'W, 940 m elev., 31 March 1977, M. Gentili, Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Buenos Aires, Argentina (MACN 35795). Verified by G. Carrizo. The specimen from Yuco was found at night crossing a dirt road, in a temperate and shady

forest of *Nothofagus obliqua* and *N. dombeyi*, with an open understory dominated by the bamboo *Chusquea culeou*. The species is endemic to the austral forests of Chile and Argentina with a narrow distribution along the eastern slopes of the Andes. In Chile, this species is distributed from the western slopes of the Cordillera de Nahuelbuta (37°18'S, 73°17'W) (Ortiz et al. 1990. Comun. Mus. Reg. Concepción 4:31–43) to Laguna San Rafael (46°40'S, 74°00'W) (Williams and Díaz-Páez 1999. Research and Conservation News [20]). In Argentina, it has thus far been recorded for a few localities at the Nahuel Huapi National Park, in southern Neuquén Province and northwestern Río Negro Province (40°47' to 41°11'S) (Vellard 1947. Acta Zool. lilloana 4:145–153; Gallardo 1962. Rev. Mus. Arg. Cienc. Nat., Bs. As. Zoología 8 [10]:113–122; Barrio and Rinaldi de Chieri 1971. Physis 30[81]:673–685), and at Los Alerces National Park in northern Chubut Province (42°50'S, 71°52'5"W) (Vellido and Úbeda 2001. Herpetol. Rev. 32:54). These two vouchers represent the first records for the Lanín National Park and extend the known range of species in Argentina ca. 70 km air line N from the previously northernmost vouchered citation, at Villa Angostura, Neuquén (Barrio and Rinaldi de Chieri, *op. cit.*). Further, this record decreases the distributional hiatus between the northern distribution limit in Chile and Argentina. The area where the voucher specimens were found is relatively rich in amphibians, and is also inhabited by *Pleurodema thaul*, *Batrachyla leptopus*, *B. taeniata*, *Eupsophus calcaratus*, *Alsodes monticola*, *Rhinoderma darwinii*, and *Bufo variegatus*.

***MANTIDACTYLUS KLEMMERI*. CORRECTION OF LOCALITY RECORD.** MADAGASCAR: CHAÎNES ANOSYENNES. Verified by Annemarie Ohler. This mantellid frog has been described from the Marojejy Massif (under the name Marojezy) in northeastern Madagascar (Guibé 1974. Bull. Mus. natn. Hist. nat. Paris 171:1171–1192). A second locality for the species, the Anosy Massif (Chaînes Anosyennes) in far southeastern Madagascar was later added (Blommers-Schlösser and Blanc 1991. Amphibiens [première partie]. Faune de Madagascar 75[1]:1–379). This was based on a voucher specimen in the Muséum national d'Histoire naturelle, Paris, catalogued as MNHN 1975.781 (Vences Glaw and Andreone 1997, Alytes 14:130–146). Later surveys failed to confirm the presence of *M. klemmeri* in this area. According to old notebooks of J. Guibé available in the MNHN the specimen was collected by Ch. P. Blanc and originally given the field number F2060. However, Blanc used a repeated numbering system in his expeditions to the Marojejy and Anosy Massifs. While one F2060 originated from "Camp IV et IIIbis" in the Chaînes Anosyennes, a second voucher with that field number came from "Marojezy 1300 m." One of these specimens was catalogued as *M. klemmeri*, a second one as *Mantidactylus microtympanum* according to Guibé's notes. Since *M. microtympanum* is a conspicuous species endemic to the southeast and has never been found in Marojejy, we are convinced that this specimen was correctly catalogued as originating from the Anosy Massif (Chaînes Anosyennes). As a conclusion, the *M. klemmeri* individual was wrongly given that locality and actually originated from the Marojejy Massif at an elevation of 1300 m. This removes one further biogeographic anomaly from the distributions of Malagasy frogs and emphasizes the high degree of endemism of the Marojejy Massif.

Submitted by **MIGUEL VENCES**, Laboratoire des Reptiles et Amphibiens, Muséum National d'Histoire Naturelle, 25 rue Cuvier, 75005 Paris, France (e-mail: m.vences@t-online.de), and **FRANK GLAW**, Zoologische Staatssammlung München, Münchhausenstr. 21, 81247 München, Germany (e-mail: frank.glaw@zsm.mwn.de).

NYCTIXALUS PICTUS (Spotted Treefrog). MALAYSIA: PENINSULAR MALAYSIA: PULAU TIOMAN; along Tekek-Juara trail (02°49'N, 104°08'E; ca. 100 m), calling while perched on leaf of sapling ca. 20 cm above ground. 16 July 2001. Tzi Ming Leong and Karen M. Crane. Raffles Museum of Biodiversity Research: Zoological Reference Collection (ZRC.1.8268, male, SVL 31.1 mm). Verified by Kelvin K. P. Lim. New island record; represents the third rhacophorid species on the island (Lim and Lim 1999. Raffles Bull. Zool. Suppl. 6:131–155). This species is also known to inhabit other islands of comparable size, such as Penang in the north, and Singapore in the south (Manthey and Grossmann 1997. Amphibien & Reptilien Südostasiens. Natur und Tier - Verlag, Münster, Germany. 512 pp.).

PHYSALAEMUS CENTRALIS (Central Dwarf Frog). BRAZIL: MINAS GERAIS: UBERLÂNDIA MUNICIPALITY (18°59'S and 48°18'W). 18 September 1999. Ariovaldo A. Giaretta. Museu de Biodiversidade do Cerrado of Universidade Federal de Uberlândia (AAG-UFU 2289). Verified by Ariovaldo A. Giaretta. Adult male (SVL 39.3 mm). First record for the state of Minas Gerais. This record confirms the presence of this species in Minas Gerais state (Brandão et al. 1997. Herpetol. Rev. 28:93). Known distribution was in the states of Mato Grosso and São Paulo, Brazil, and in northeastern Paraguay (Frost 1995. Amphibian Species of the World. Version 2/95. Electronic Manuscript. Herpetologists' League). All the reports confirm the presence of this species in Cerrado Bioma Domain and not in the Atlantic Forest Domain (Duellman 1999. *In* Duellman [ed.], Patterns of Distribution of Amphibians. A Global Perspective, pp. 255–328. Johns Hopkins Univ. Press).

Submitted by **MARCELO N. DE C. KOKUBUM** and **MARCELO MENIN**, Laboratório de Ecologia e Sistemática de Anuros Neotropicais, Programa de Pós-Graduação em Ecologia e Conservação de Recursos Naturais, Universidade Federal de Uberlândia, 38400-902, Uberlândia, Minas Gerais, Brazil; e-mail (MNK): mkokubum@bol.com.

POLYPEDATES COLLETTI (Hourglass Treefrog). MALAYSIA: PENINSULAR MALAYSIA: JOHOR; 7 km east of Jemaluang (02°16'N, 103°50'E; ca. 50 m), forest beside road, perched low on

understory vegetation. 6 July 2001. L. Lee Grismer and Jesse L. Grismer. Raffles Museum of Biodiversity Research: Zoological Reference Collection (ZRC.1.8228, female, SVL 73.2 mm; ZRC.1.8229, male, SVL 51.5 mm; ZRC.1.8230, male, SVL 48.3 mm). Verified by Kelvin K. P. Lim. New state record, in addition to Selangor, Pahang, and Negri Sembilan (Berry 1975, The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp.). Southeasterly range extension of ca. 185 km (from Pasoh Forest Reserve, Kuala Pilah, Negri Sembilan).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-mail: scip0132@nus.edu.sg), **L. LEE GRISMER** and **JESSE L. GRISMER**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

PSEUDACRIS CRUCIFER. USA: WISCONSIN: KEWAUNEE CO: NW 1/4 Sec. 8, T23N, R24E, Lipsky Swamp State Wildlife Area (44°28'45"N 87°37'15"W). 14 April 2001. Melissa Saeland. UWSP Herp 3933 - female and UWSP Herp 3934 - male. Verified by Erik Wild. Specimen 3933 had a SVL of 33.2 mm, weight = 1.9 g; specimen 3934 had a SVL of 24.6 mm, weight = 1.7 g. First county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Museum. 87 pp.).

Submitted by **MELISSA J. SAELAND**, Department of Biology, University of Wisconsin - Stevens Point, Stevens Point, Wisconsin 54481, USA (e-mail: msael739@uwsp.edu), and **MARK W. DOPERALSKI**, University of Wisconsin - La Crosse, La Crosse, Wisconsin 54601, USA.

PSEUDACRIS MACULATA. USA: MONTANA: GLACIER CO: Glacier National Park, temporary wetland (48°24'55"N, 113°14'48"W) in the Railroad Creek drainage. 15 July 2001. B. H. Hossack and K. J. Yale. Deposited in the Glacier National Park Museum (GLAC 22540). Verified by P. S. Corn. *P. maculata* had not previously been found in Glacier National Park (Marnell 1997. Northwest. Nat. 78:17–33), although it had been collected outside the park less than 5 km from the current collection site. Specimen was collected under permit GLAC-2001-SCI-0004.

RHACOPHORUS BIPUNCTATUS (Twin-spotted Treefrog). MALAYSIA: PENINSULAR MALAYSIA: SELANGOR-PAHANG border, Genting Highlands (03°46'N, 101°47'E; ca. 1750 m). June 2001. Oh Kim Sang. Raffles Museum of Biodiversity Research: Zoological Reference Collection (ZRC.1.8061, male, SVL 40.2 mm; ZRC.1.8062, female, SVL 61.9 mm; ZRC.1.8063, female, SVL 57.7 mm; ZRC.1.8064, female, SVL 60.1 mm; ZRC.1.8065, female, SVL 61.8 mm). Verified by Kelvin K. P. Lim. Previously known from only three montane localities: Bukit Larut (Perak), Cameron Highlands (Perak-Pahang border), and Fraser's Hill (Selangor-Pahang border) (Berry 1975. The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. x + 130 pp.). This is a new montane locality record and represents a southerly range extension of ca. 40 km (from Fraser's Hill).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-mail: scip0132@nus.edu.sg), **NORSHAM SUHAINA YAAKOB**, Forest Research Institute Malaysia, Kepong, 52109 Kuala Lumpur, Malaysia, and **BOO LIAT LIM**, Department of Wildlife and National Parks (Peninsular Malaysia), Km 10, Jalan Cheras, 561000 Kuala Lumpur, Malaysia.

RHACOPHORUS EXECHOPYGUS (Spinybottom Tree Frog). VIETNAM: QUANG NAM PROVINCE: Ngoc Linh Mountain Range, Tra My District, 980–1020 m elev. (15°11'41"N, 108°02'25"E). Nguyen Quang Truong. Verified by Robert F. Inger. American Museum of Natural History (AMNH A-163707). First provincial record for Quang Nam (Inger et al. 1999. Fieldiana Zool. 92, pp.12–13, Fig. 4).

Submitted by **RAOUL BAIN**, Center for Biodiveristy and Conservation, American Museum of Natural History, Central Park West at 79th Street, New York, NY, 10024, USA, and **NGUYEN QUANG TRUONG**, Department of Zoology, Institute of Ecology and Biological Resources, Hoang Quoc Viet St., Cau Giay, Hanoi, Vietnam.

RHOMBOPHRYNE TESTUDO. CORRECTION OF LOCALITY RECORD. MADAGASCAR: RÉUNION. Verified by Annemarie Ohler. This endemic Malagasy microhylid frog has been reported from Réunion Island (Guibé 1978. Les Batraciens de Madagascar. Bonn. zool. Monogr. 11:1–140) but this locality was later doubted (Blommers-Schlösser and Blanc 1991, Amphibiens [première partie]. Faune de Madagascar 75[1]:1–379). However, the source of this confusion has never been clarified. The record was almost certainly based on a voucher in the Muséum National d'Histoire Naturelle, Paris (MNHN 1829), recently revised by us. According to the original entry in the regular catalogue, it originated from "Île de la Réunion," but according to the glass label from "Nossi Bé: Mus. de Saint-Denis." Nosy Be is the type locality of *R. testudo*. An old catalogue in the Paris museum refers to the same specimen (entry 1869.104) as originating from "Nossi-Be et Nossi-Cumba (Madagascar)" and having been granted in exchange by the "Commission Scientifique de Bourbon" (Bourbon being an old name of Réunion). Apparently this information was omitted when the data were copied to the regular catalogue. We therefore conclude that the species does not occur outside Madagascar. The locality "Sambava-Andapa" in the map of Blommers-Schlösser and Blanc (1991) is corroborated by the well-preserved specimen MNHN 1973.576, confirming that *R. testudo* is not restricted to its type locality. However, the locality "Marojezy" given by the same authors and by Guibé (1978) is not corroborated by any voucher and probably refers to the same specimen MNHN 1973.576 which is catalogued as originating from "Sambava, km 17 route d'Andapa (massif Marojezy)," having been collected on 19 December 1972 (see also Blommers-Schlösser and Blanc 1991, p. 92).

Submitted by **FRANK GLAW**, Zoologische Staatssammlung München, Münchhausenstr. 21, 81247 München, Germany (e-mail: frank.glaw@zsm.mwn.de) and **MIGUEL VENCES**, Laboratoire des Reptiles et Amphibiens, Muséum National d'Histoire Naturelle, 25 rue Cuvier, 75005 Paris, France (e-mail: m.vences@t-online.de).

SCAPHIOPUS COUCHII (Couch's Spadefoot). USA: ARIZONA: NAVAJO CO: 2 specimens: State Hwy 87, 14.5 km NE of Jct. with I-40 (at Winslow N35°6.37' W110°31.64', 1600 m elev.), UTA A-53914; and 28.6 km NE of jct. with I-40 (N35°12.03' W110°26.32', 1700 m elev.), UTA A-53915. 10 August 1999. Daniel G. Mulcahy and Kirk W. Setser. Verified by Paul C. Ustach. Both specimens were found alive on the road, during a light rain at 2237 and 2305 h respectively. These specimens represent new county records. Closest known record is one specimen (MVZ 66242) collected in 1957 on U.S. Hwy 260, near Petrified Forest, Apache Co., Arizona (ca. 70 km). These specimens represent the second and third records of this species found north of the Mogollon Rim in Arizona, which may indicate this species is more widespread in this portion of the Colorado Plateau as indicated by Stebbins (1985, Peterson Field Guide to Western Reptiles and Amphibians, Second ed. Houghton-Mifflin, Boston, Massachusetts. 336 pp.). On this same evening, the following anurans were also collected along this highway and deposited at UTA: *Spea bombifrons* (A-53919–20), *S. multiplicata* (A-53918) and *Bufo cognatus* (A-53921–22). These species have all been collected at ca. 30 km to the east, along Hwy 77 north of I-40, Navajo Co., Arizona (specimens at CAS).

Submitted by **DANIEL G. MULCAHY** (e-mail: dmulcahy@biology.usu.edu) and **KIRK W. SETSER** (e-mail: setser@biology.usu.edu), Department of Biology, Utah State University, Logan, Utah 84322-5305, USA.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). USA: INDIANA: POSEY CO: 2.0 Km N Griffin. 5 June 2001. Eugene Mumford. Carnegie Museum Natural History (CMNH Accession 36774). Verified by John Weins. Adult male photographed—one of several recent records from loess hill uplands of Bethel Township, near Wabash River. New county record and first record for southwestern "pocket" of Indiana (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Acad. Sci. 404 pp.) and first record from adjacent region of Illinois (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Natural History Survey Manual 8. 300 pp.) and from the adjacent

western coal field of Kentucky (John R. MacGregor, pers. comm.).

Submitted by **MICHAEL J. LODATO**, 925 Park Plaza Drive, Evansville, Indiana 47715-4428, USA, and **BISHOP MUMFORD** and **EUGENE MUMFORD**, P.O. Box 50, Griffin, Indiana 47616, USA.

TESTUDINES

CHELYDRA SERPENTINA (Common Snapping Turtle). USA: MICHIGAN: Charlevoix Co: Garden Island (N45°47.90' W85°30.39'), washed up (deceased) on the far eastern shore of Indian Harbor. 14 May 2001. Kenneth D. Bowen. Verified by Nancy E. Seefelt. Central Michigan University Museum of Culture and Natural History (CMU R-1558). First verified record of this animal for Garden Island.

Submitted by **KENNETH D. BOWEN** and **JAMES C. GILLINGHAM**, Department of Biology, Central Michigan University, Mt. Pleasant, Michigan 48859, USA.

CHRYSEMYS PICTA (Painted Turtle). USA: MICHIGAN: Charlevoix Co: Garden Island (N45°47.90' W85°30.39'), found trapped (deceased) in a fishing net in Indian Harbor. 21 June 2001. Michael Sieder. Verified by Nancy E. Seefelt. Central Michigan University Museum of Culture and Natural History (CMU R-1561). First verified record of this animal for Garden Island.

Submitted by **KENNETH D. BOWEN** and **JAMES C. GILLINGHAM**, Department of Biology, Central Michigan University, Mt. Pleasant, Michigan 48859, USA

KINOSTERNON HERRERAI (Herrera's Mud Turtle). MÉXICO: MÉXICO: Municipality of Temascaltepec, El Tule, on the bank of Temascaltepec River (19°00'N, 100°05'W), 1520 m elev. 17 May 1999. Vicente Mata-Silva and Martín Paredes-Flores. Laboratorio de Ecología, Unidad de Biología, Tecnología y Prototipos, FES-Iztacala, Universidad Nacional Autónoma de México (VMS 235). Verified by Edmundo Pérez-Ramos. First record for the state of México (Camarillo-R. and Smith 1992. *In* Strimple and Strimple [Eds.], Contributions in Herpetology, pp. 39–41. Greater Cincinnati Herpetological Society, Cincinnati, Ohio. viii + 111 pp.). Closest record for this species is from the Gulf lowlands in the state of Hidalgo (Iverson 1992. A Revised Checklist with Distribution Maps of the Turtles of the World. Privately printed, Richmond, Indiana. viii + 363 pp.).

Submitted by **VICINTE MATA-SILVA, AURELIO RAMIREZ-BAUTISTA, MARTIN PAREDES-FLORES**, and **MANUEL ESPINO-OCAMPO**, Laboratorio de Ecología, UBIPRO, Facultad de Estudios Superiores-Iztacala, UNAM, Apdo. MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle). USA: LOUISIANA: Calcasieu Parish: Little River, a small tributary of the West Fork Calcasieu River (N30°19.342, W93°17.843). 23 June 2001. Avery A. Williams. Louisiana State University at Eunice Vertebrate Collection (LSUE 583). Verified by Steve Shively. First Parish record as mapped by Dundee and Rossman (1989. The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.). Although commercial and recreational trappers in Southwest Louisiana have commonly collected this species, the above record represents the only known museum specimen from Calcasieu Parish. This specimen was trapped in a turtle hoop net baited with canned sardines.

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

LACERTILIA

DAREVSKIA VALENTINI (Caucasian Rock Lizard). USA: OHIO: Van Wert Co: west Delphos at Kill Brothers Equipment Company on Ohio Rt. 697. August 1986. KU 206727. Misidentified as *Podarcis muralis;* was re-identified by comparing size and scale counts to other members of the genus. SVL 70 mm; exceeds that of *P. muralis*. *Darevskia* is distinguished from *Podarcis* by alternating narrow and broad whorls of scales around tail and keeled scales on tibia and tail. Home range of *D. valentini* comprises southern Georgia, Armenia, and northeastern Turkey at elevations from 1700–3000 m. (Conant and Collins 1998. Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Company, Boston, Massachusetts. 616 pp.; Darevsky 1967. Skalnye jasczcerizy Kawzaka. Akademii Nauk, Leningrad, 214 pp.; Bischoff and Deichsel, ms. in prep.)

DRACO QUINQUEFASCIATUS. SINGAPORE: Bukit Timah Nature Reserve. 13 March 2001. Tim Youmans, Jesse Grismer, and Geoff Powels. La Sierra University Photo Collection (LSUPC) L-3296-97. Verified by L. Lee Grismer. Previously known from West Malaysia, southern Thailand, Sumatra, Pulau Singkep, Pulau Belitung, and Borneo (Manthey and Grossmann 1997. Amphibien and Reptilien Südostasiens. Natur und Tier-Verlag, Münster, Gemany. 512 pp.). New island record. One male was found during mid-afternoon on a large dipterocarp tree (at a position ca. 2 m from the ground) along a walking trail in the primary forest with closed canopy. This individual was captured, photographed, and released.

Submitted by **JESSE L. GRISMER** (e-mail: jessgris@lasierra.edu), **GEOFF POWELS**, and **TIM YOUMANS**, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

HEMIDACTYLUS FRENATUS (Common House Gecko). EL SALVADOR: LA LIBERTAD: Rancho Belmar near La Libertad. Unknown date. M. Mueke. LACM 9375. Verified by Roy McDiarmid. New record for El Salvador (Dueñas et al. 2001. *In* Johnson et al. [eds.], Mesoamerican Herpetology: Systematics, Zoogeography, and Conservation, pp. 93–99. Centennial Museum Spec. Publ. No. 1, The University of Texas at El Paso, El Paso).

This introduced species has been reported from several Central American countries, but the closest locality is from the Pacific versant of Guatemala (Stuart 1963. A Checklist of the Herpetofauna of Guatemala. Misc. Publ. Mus. Zool. Univ. Michigan [122]:1–150).

Submitted by **ELI GREENBAUM**, Division of Herpetology, Natural History Museum and Biodiversity Research Center, The University of Kansas, 1345 Jayhawk Blvd., Lawrence, Kansas 66045-7561, USA; e-mail: elig@ku.edu.

HEMIDACTYLUS TURCICUS. USA: NEW MEXICO: SIERRA Co: Downtown Truth or Consequences, The Charles Motel and Spa, 601 Broadway, New Mexico, USA; N33°7.718' W107°15.491'. Adult and juvenile. 18 September 1999. Don S. Sias and Pete E. Humphrey. University of New Mexico Museum of Southwestern Biology (MSB 62809–810). Verified by Charles W. Painter. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, xix + 431 pp.). Extends the distribution in New Mexico approximately 101 km to the NNW from the Las Cruces population (Painter et al. 1992. Herpetol. Review 23:62). Thirty additional individuals were observed of all size classes in the vicinity of the hotel.

Submitted by **DON S. SIAS**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA, and **PETE E. HUMPHREY**, University of New Mexico School of Medicine, Albuquerque, New Mexico 87131, USA

OPHISAURUS SOKOLOVI (Sokolov's Glass Lizard). VIETNAM: QUANG NAM PROVINCE: Ngoc Linh Mountain Range, Tra My District, 860 m elev. (15°11'41"N, 108°02'25"E). Nguyen Quang Truong. Verified by Nikolai Orlov. Institute of Ecology and Biological Resources, Hanoi, Vietnam (IEBR 102). First provincial record for Quang Nam (Darevsky and Nguyen 1983. Zool. Zh. 62[12]:1827–1837).

Submitted by **RAOUL BAIN**, Center for Biodiveristy and Conservation, American Museum of Natural History, Central Park West at 79th Street, New York, New York, 10024, USA, and **NGUYEN QUANG TRUONG,** Department of Zoology, Institute of Ecology and Biological Resources, Hoang Quoc Viet St., Cau Giay, Hanoi, Vietnam.

TROPIDURUS HISPIDUS. BRAZIL: PARÁ: Municipio de Monte Alegre, Serra do Erere, Morro da Lua (2°01'49"S and 54°12'21"W, 135 m), left bank of the Rio Amazonas. J. G. da Frota and R. N. Yuki. 23 September 2001. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Pará, Brazil (LPHA 1819–1820, LPHA 1830–31). Verified by Andrei G. Guedes. For Amazonia, the species is known from Manaus city (Amazonas State), eastern limit of Maranhão and eastern Pará; for enclaves of open vegetation north of the Amazon River, in Roraima, southern part of French Guiana (Tumuc-Humac Mountains), Suriname, Guyana, and Venezuela. These specimens represent the first record from western Pará and fill a distributional gap of ca. 1359 km between the known localities. Enlarges the known distribution ca. 688 km from Castanhal to the west, ca. 672 km from Manaus to the east; and ca. 567 km from Tumuc-Humac Mountains at south, and corroborates the hypothesis of Rodrigues (1987. Arq. Zool. 31[3]:105–230), that all *Tropidurus* populations north of the Rio Amazonas are *T. hispidus* (Ávila-Pires 1995. Lizards of Brazilian Amazonia (Reptilia: Squamata). Zool. Verh. [299]:1–706).

Submitted by **MÁRCIA LIA DE SOUSA ABREU**, **JOSSEHAN GALÚCIO DA FROTA** and **RUBENS NOBUO YUKI**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200; e-mail (MLS): marcialiaa@bol.com.br.

TROPIDURUS OREADICUS. BRAZIL: PARÁ: Municipio de Santarém, Barreira do Tapará (02°10'S and 54°31'W), left bank of the Rio Amazonas. M. S. S. Neves, 6 October 2001. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Santarém, Pará State (LPHA 1858). Verified by Rubens N. Yuki. In Brazil, this species occurs in the cerrados of Mato Grosso, Mato Grosso do Sul, Minas Gerais, Goiás, Maranhão, and Rondônia. Along the lower Tocantins River to Belém (Pará). It also occupies some enclaves of open vegetation in the Amazonian region south of the Amazon River (e.g., in Serra dos Carajás, southern Pará). These specimens represent the first record north of the Amazon River, western Pará, enlarges western distribution ca. 540 km (airline) from reservoir area of hydroelectric dam Tucuruí and ca. 580 km (airline) east from Porto Velho. (Ávila-Pires 1995. Lizards of Brazilian Amazonia (Reptilia: Squamata). Zool. Verh. [299]:1–706; Rodrigues 1987. Arq. Zool. 31[3]:105–230).

Submitted by **ALFREDO PEDROSO DOS SANTOS, JR.** (e-mail: alphredojr@mailbr.com.br), **MÁRCIA LIA DE SOUSA ABREU**, and **JOSSEHAN GALÚCIO DA FROTA**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200.

SERPENTES

ANILIUS SCYTALE. VENEZUELA: MÉRIDA: CBX 13 Island, Borde Seco Dam (07°44'30"N, 71°32'50"W). 21–22 September 2001. Grupo Ecología Animal 2001. Colección de Vertebrados, Universidad de los Andes, Facultad de Ciencias (CVULA IV-6344–45). Verified by D. Cadena. First state record, north of Orinoco River and westernmost in Venezuela, ca. 430 km NW of the closest record, sector Gavilán, Puerto Ayacucho, Amazonas (Rodríguez-Acosta and Fuentes 1995–96. Terra 11–12:77–84). *Anilius scytale* was known from several localities in Venezuela, all south of the Orinoco River (Roze 1966. La Taxonomía y Zoogeografía de los Ofidios de Venezuela. Ediciones de la Biblioteca, Universidad Central de Venezuela, Caracas. 360 pp; Lancini 1979. Serpientes de Venezuela. Armitano Ed., Caracas; Lancini and Kornacker 1986. Die Schlangen von Venezuela. Verlag Armitano, Caracas). This locality shows a wider distribution in Venezuela, not restricted to the southern Orinoco area ("región guayanesa" and "región deltaica" in Barrio (1998. Acta Biol. Venez. 18[2]:1–93), as expected in Hoogmoed (1979. *In* Duellman (ed.), The South American Herpetofauna: its Origin, Evolution and Dispersal, pp. 241–279. Mus. Nat. Hist. Univ. Kansas Monogr. 7). Rainforests in piedmont of the Cordillera de Mérida

(Venezuelan Andes) between 250 m and 1000 m, show a wide biogeographical array, with elements shared from four very different bio-regions: "región andina, región orocostense, región llanera," and "región amazónica," as pointed out by Barrio (*op. cit.*) for amphibians.

Submitted by **CÉSAR LUIS BARRIO**, Fundación AndígenA, Apartado Postal 210, 5101-A, Mérida, Venezuela (e-mail: cesarlba@yahoo.com), **ANDRÉS CHACÓN** and **AMELIA DÍAZ DE PASCUAL**, Facultad de Ciencias, Universidad de los Andes, Mérida, Venezuela (e-mail: aecortiz@yahoo.com and adiaz@ciens.ula.ve).

CHIRONIUS EXOLETUS (Green Keeled Racer). BRAZIL: PARÁ: Municipio de Monte Alegre, Serra do Erere, Morro da Lua (2°01'49"S, 54°12'21"W, 148 m), left bank of the Amazônas River, J. G. da Frota, 23 September 2001. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 1818; female; 1340 mm). Verified by Andrei G. Guedes. The species was known from the east coast of Brazil, northeastern Argentina, and equatorial South America including Amazonian Brazil (is common in the east and south of the state of Pará), Bolivia, eastern Peru and Surinam, and French Guiana; it also occurs at higher elevations in western Ecuador and Colombia, Panama, and Costa Rica. This specimen represents the first record for northwestern Pará, and the distribution of the species becomes more homogeneous. Using airline distances, the Monte Alegre record is between three localities known for the species: it is to the northeast of the Comunidade de São Luis do Tapajós (ca. 349 km); is to the west of the city of Belém (ca. 639 km), and is to the southwest of the city of Cayenne (ca. 801 km) (Cunha and Nascimento 1982. Bol. Mus. Para. Emílio Goeldi, Nov. Sér. Zool. [119]:1–17; Dixon et al. 1993. Revision of the Neotropical Snake Genus *Chironius* Fitzinger [Serpentes, Colubridae] – Monografie XIII. Torino: Museo regionale di scienze naturali, 1–279).

Submitted by **JOSSEHAN GALÚCIO DA FROTA** (e-mail: jgfrota@mailbr.com.br) and **RUBENS NOBUO YUKI**, Linha de Pesquisa em Herpetologia da Amazônia (LPHA), Laboratório de Pesquisas Zoológicas (LPZ), das Faculdades Integradas do Tapajós (FIT), Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200.

CROTALUS HORRIDUS (Timber Rattlesnake). USA: LOUISIANA: Calcasieu Parish: The area of Sabine River Bridge (Hwy I-10). June 1992. A. Nelly. Seale Museum of Louisiana, McNeese State University (SML 9273). Verified by Steve Shively. First parish record. This specimen represents the southern and westernmost record in the state as mapped by Dundee and Rossman (1989. The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

DRYMOBIUS RHOMBIFER. VENEZUELA: BARINAS: Barinitas city, 550 m. 7 July 2001. H. Sánchez. Colección de Vertebrados, Universidad de los Andes, Mérida (CVULA 6427). Verified by Yoel Morales. This rare species is known in Venezuela from two disjunct localities, the Sierra de Perijá in NW extreme of the country, bordering with Colombia, and the Amazon rainforest (Lancini 1979. Serpientes de Venezuela. Armitano Ed., Caracas; Lancini and Kornacker 1986. Die Schlangen von Venezuela. Verlag Armitano, Caracas; Roze 1966. La Taxonomía y Zoogeografía de los Ofidios de Venezuela. Ediciones de la Biblioteca, Universidad Central de Venezuela, Caracas). This locality reduces the gap between these very different bio-regions. Thus, *D. rhombifer* shows a wider distribution in Venezuela than previously considered, from the Amazon to Perijá along rainforests in Andean foothills.

Submitted by **DANIEL CALCAÑO**, Serpentarium Los Llanos, Barinitas, Barinas, Venezuela (e-mail: reprecal@cantv.net) and **CESAR L. BARRIO-AMORÓS**, Fundación AndígenA. Apartado Postal 210. Mérida 5101-A, Venezuela (e-mail: cesarlba@yahoo.com).

EPICRATES CENCHRIA MAURUS (Rainbow Boa). BRAZIL: PARÁ: Municipio de Almeirim, Missão Jesuita Tiriós (02°15'N, 55°59'W). 19 October 1979. Verified by V. J. Germano. Herpetological Collection "Alphonse Richard Hoge" of Instituto Butantan, São Paulo, S.P., Brazil (IB 42745, sub adult and IB 42746, juvenile). First record of this subspecies from Brazil. The nearest localities are: Caiena, French Guiana, ca. 420 km NE and, in the vicinity of Nickerie city, Surinam, ca. 410 km NW (Abuys 1989. Litteratura Serpentium 9[3]:126–128; Chippaux 1986. Les Serpents de la Guyane Française. Paris, Orstom. 156 pp.; Roze 1966. La Taxonomia y Zoogeografia de los Ofídios en Venezuela. Caracas, Biblioteca Central Univ. Central Venezuela. 362 pp.)

Submitted by **PAULO PASSOS**, Museu Nacional, Quinta da Boa Vista, CEP: 20940-040, Rio de Janeiro, R.J., Brazil (e-mail: ppassos@mn.ufrj.br) and **FRANCISCO LUÍS FRANCO**, Laboratório de Herpetologia, Instituto Butantan, Av. Vital Brazil, 1500, CEP: 05503-900, São Paulo, S.P., Brazil (e-mail: flfrancobuta@hotmail).

GONATODES CONCINNATUS LIGIAE: VENEZUELA: APURE: 7 km NE La Victoria, distrito Páez. 29 April 1987. R. Rico. Colección de Vertebrados, Universidad de los Andes, Mérida (CVULA 5032). An adult male verified by Gilson Rivas. First state record and third for the country, ca. 160 km SSE of previous published records for Barinitas and Reserva Forestal Ticoporo, in the state of Barinas (Rivero-Blanco 1967 "1968." Mem. Soc. Cien. La Salle 27:104–119). This subespecies was predicted to occur in Apure (Rivero-Blanco 1979. The Neotropical Lizard Genus *Gonatodes* Fitzinger [Sauria: Sphaerodactylinae]. Ph.D. dissertation, Texas A&M University. 224 pp.). The species inhabits all piedmont rainforest and gallery forest areas in adjacent Llanos from Perú to Venezuela (Peters and Donoso-Barros 1986. Catalogue of the Neotropical Squamata. Part II. Lizards and Amphisbaenians. Smiths. Inst. Press. Washington, D.C.).

Submitted by **CARLOS RIVERO-BLANCO**, C.R.B. Ecólogos Consultores C.A., Apartado 63011, Chacaito, Caracas 1067-A, Venezuela (e-mail: carivero@telcel.net.ve) and **CÉSAR L. BARRIO-AMORÓS**, Fundación Andígena, Apartado Postal 210, Mérida 5101-A, Venezuela (e-mail: cesarlba@yahoo.com).

HYPSIGLENA TORQUATA. (Night Snake) USA: IDAHO: Cassia Co: CR G3 (Rock Creek Rd.), 20 m N of Sawtooth National Forest, Rock Creek, (N42°19.93' W114°16.80'), 1400 m elev. 28

August 1999. Kirk W. Setser. UTA R-51097. Verified by Paul C. Ustach. Specimen was found alive on the road at 2148 h. The road went through mixed grass/sagebrush with scattered rocks and was within 30 m of Rock Creek. It was partly cloudy, and between 18–21°C. This is a new county record (Laurence and Reynolds 1984. Great Basin Nat. 44[2]:313–316). Most distribution maps show this species continuous from Pocatello, Idaho to Oregon. The closest actual records are from: Pocatello, Bannock Co., Idaho (ca. 160 km); near Craters of the Moon Nat'l. Mon., Blaine Co., Idaho (ca. 120 km); near Grand View, Elmore Co., Idaho (ca. 160 km) (Linder and Fichter 1977. The Amphibians and Reptiles of Idaho, Idaho State Univ. Press, Pocatello, Idaho; Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest, Univ. of Idaho Press, Moscow, Idaho). This species' range is probably continuous throughout this area, however records are lacking.

Submitted by **DANIEL G. MULCAHY** (e-mail: dmulcahy@biology.usu.edu) and **KIRK W. SETSER** (e-mail: setser@biology.usu.edu) Department of Biology, Utah State University, Logan, Utah 84322-5305, USA.

LAMPROPELTIS TRIANGULUM (Milk Snake). USA: MICHIGAN: Charlevoix Co: Garden Island (N45°47.90' W 85°30.39'), found under a large sheet of plastic on the north side of Graham's Point. 14 May 2001. Kenneth D. Bowen. Verified by Nancy E. Seefelt. Central Michigan University Museum of Culture and Natural History (CMU R-1562). First verified record of this animal for Garden Island.

Submitted by **KENNETH D. BOWEN** and **JAMES C. GILLINGHAM**, Department of Biology, Central Michigan University, Mt. Pleasant, Michigan 48859, USA.

LEPTOTYPHLOPS DULCIS (Texas Blind Snake). USA: NEW MEXICO: Lincoln Co: Adjacent to north side of Highway 70/380 mile marker 298 (.5); N33°20.454', W105°4.352'. Three snakes. 16 June 1999. Don S. Sias. University of New Mexico Museum of Southwestern Biology (MSB) 62812–14. Verified by Charles W. Painter. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, xix + 431 pp.). Extends range west into the Sacramento Mountain foothills from Pecos River Valley records.

Submitted by **DON S. SIAS**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

LIOPHIS EPINEPHELUS OPISTHOTAENIUS. VENEZUELA: FALCÓN: Municipio Petit: Curimagua. 1 August 1982. M. González Sponga. Museo de Ciencias Naturales, Caracas (MCNC 7705). Verified by L. F. Navarrete. First state record and northeasternmost locality in South America (Dixon 1983. *In* Rhodin and Miyata [eds.], Advances in Herpetology and Evolutionary Biology, pp. 132–149. Mus. Comp. Zool., Harvard Univ.; Mijares-Urrutia and Arends. 2000. Smithson. Herpetol. Infor. Serv. 123:1–30). In Venezuela, this species was known from Cordillera de Mérida, Venezuelan Andes (Roze 1966. La Taxonomía y Zoogeografía de los Ofidios en Venezuela. Univ. Central de Venezuela. Edic. Biblioteca. Caracas, 362 pp.). This locality reveals a wider distribution of this species throughout the Venezuelan Coastal Range (including now the Lara-Falcón mountain system), east of the Andes (Dixon, *op. cit.*).

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Apartado Postal 1930, Caracas 1010-A, Venezuela (e-mail: gilsonrivas@mixmail.com), and **OSWALDO FUENTES**, 19135 US 19 North, Apt. J8, Clearwater, Florida 33764, USA.

LIOPHIS MILIARIS CHRYSOSTOMUS. BRAZIL: PARÁ: Municipio de Tirios. A. Silva-Filho. 2001. Linha de Pesquisa em Herpetologia da Amazônia (LPHA), Laboratório de Pesquisas Zoológicas (LPZ), Faculdades Integradas do Tapajós, Santarém, Pará State (LPHA 1854). Verified by R. Nobuo Yuki. Species known from dense rainforests of lowland Amazonian parts of Brazil, Colombia, Ecuador, and Peru. First record from northern Amazonas River in the Pará, enlarges the known distribution ca. 420 km airline from the nearest record (Municipio Obidos), also in Pará. (Dixon 1983. Copeia 1983:791–802; Dixon 1989. Smithson. Herptol. Infor. Serv. 79:1–28).

Submitted by **JOSSEHAN GALÚCIO DA FROTA** (e-mail: jgfrota@mailbr.com.br) and **ALFREDO PEDROSO DOS SANTOS, JR**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Santarém, Pará, Brazil, CEP: 68.010-200.

LIOPHIS POECILOGYRUS SCHOTTI. VENEZUELA: AMAZONAS: Puerto Ayacucho: Atures, 75 m. 14 September 1979, P. Piñate. Museo de la Estación Biológica de Rancho Grande, Aragua (EBRG 1157, adult male); specimen without date, J. Sánchez and F. Guánchez (EBRG 1750, adult female); 28 July 1985, J. Sánchez. (EBRG 1916, adult female); 23 August 1982, J. Sánchez and P. Piñate (EBRG 1652, adult male); 19 November 1978, E. Armas (EBRG 1543, adult female). Mavaca, upper Orinoco River, May 1979, J. Finkers (EBRG 3048, juvenile). First state records. All specimens verified by César R. Molina. EBRG 3048 is the southernmost known record in Venezuela. *Liophis poecilogyrus* was mentioned as a possible inhabitant in Venezuela by Dixon (1989. Smithson. Herpetol. Inform. Serv. 79:1–28). Dixon and Markezich (1992. Texas J. Sci. 44:131–166), pointed out in their map two points in Bolívar state, without locality data. Later, Fuentes and Barrio (1999. Herpetol. Rev. 30:54) confirmed its presence in Bolívar state. In this note we assign the Venezuelan population to the subspecies *L. p. schottii* and expand the known range about 600 km to the southwest. Puerto Ayacucho is a town surrounded by Guianan savanna. *Liophis poecilogyrus* is a savanna dweller, but Mavaca is the first Amazon rainforest locality for this species in Venezuela.

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Apartado Postal 1930, Caracas 1010-A, Venezuela, **OSWALDO FUENTES**, 19135 US 19 North, Apt. J8, Clearwater, Florida 33764, USA, and **CÉSAR L. BARRIO**, Fundación AndígenA, Apartado Postal 210, 5101-A Mérida, Venezuela.

MASTICOPHIS FLAGELLUM TESTACEUS (Western Coachwhip). MÉXICO: CHIHUAHUA: Cañon de Barrera, Ejido El Álamo, 1.0 km NW Rancho El Fortín, by Río Conchos (29°32'36.4"N, 104°52'23.0"W), 939 m elev. 20 June 2000. Herpetological collection of Unidad de Biología, Tecnológico y Prototipos (UBIPRO 5497). Verified by Richard L. Holland. First

record for Chihuahua and a slight range extension from localities in the Big Bend region of Texas (Wilson 1970. Tulane Stud. Zool. Bot. 16:31–99), although an intergrade with *M. f. lineatulus* farther southwest was reported by Lemos-Espinal et al. (2000. Bull. Chicago Herpetol. Soc. 35:19–24). All other records for Chihuahua are for *M. f. lineatulus*.

PHILODRYAS PATAGONIENSIS. BRAZIL: RONDÔNIA: Município de Ouro Preto do Oeste (10°44'S 62°13'W). October 1983. E. Roppa. Museu Nacional, Rio de Janeiro, Brazil (MNRJ 8445, young specimen). Verified by R. Fernandes. First state record, extends the known distribution ca. 830 km northeast of Cochabamba, Bolivia (Thomas 1976. Unpubl. Ph.D. thesis, Texas A&M University, College.Station).

Submitted by **PAULO PASSOS** (e-mail: ppassos@mn.ufrj.br) and **DANIEL S. FERNANDES** (e-mail: danfer@acd.ufrj.br), Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista s/n, Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil.

PSAMMOPHIS SIBILANS SIBILANS (African Beauty Snake). EGYPT: SUEZ CANAL AREA: ISMAILIA PROVINCE: Al-Ababdah, Serapeum (30°29'44"N, 32°19'02"E). 2 June 2001. Adel A. Ibrahim. Muséum National d'Histoire Naturelle, Paris (MNHN 2001.0601). Verified by Ivan Ineich. A female (660 mm SVL) freshly killed by a farmer at site immediately close to a creek. Two other individuals were also observed in July 2001 at Suez City (29°58'05"N, 32°32'12"E), and at Al-Ganayen, ca 10 km N of Suez City (31°05'47"N, 33°40'06"E). In Egypt, this snake is well known from the Nile Delta as far as Aswan in the upper Egypt. In western desert, only a single record was reported from Matruh (Marx 1968. Checklist of the Reptiles and Amphibians of Egypt. U.S. Naval Medical Research Unit No. III, Cairo, 51 pp.). First record for the Suez Canal area (Saleh 1997. Amphibians and Reptiles of Egypt. Publ. National Biodiversity Unit. No. XI, 234 pp.).

Submitted by: **ADEL A. IBRAHIM**, Department of Biological Sciences and Geology, Faculty of Education at Al-Arish, Suez Canal University, North Sinai, Egypt; e-mail: aibrahim@ismailia.ie-eg.com.

PSOMOPHIS JOBERTI. BRAZIL: AMAZONAS: Município de Benjamin Constant (4°22'S 70°02'W). 1942. A. Parko. Museu Nacional, Rio de Janeiro, Brazil (MNRJ 1293, adult male 241 mm SVL, 65 mm TL). Verified by R. Fernandes. First state record, extends the known range ca. 2310 km northwestern of Barra do Tapirapés, state of Mato Grosso and about 2200 km west of Marajó Island, state of Pará (Myers and Cadle 1994. Am. Mus. Novitates 3102:1–33).

Submitted by **PAULO PASSOS** (e-mail: ppassos@mn.ufrj.br) and **DANIEL S. FERNANDES** (e-mail: danfer@acd.ufrj.br), Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista s/n, Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil.

THAMNOPHIS MELANOGASTER CHIHUAHUAENSIS (Chihuahuan Black-Bellied Garter Snake). MÉXICO: DURANGO: ca. 2 air km N and 12 km W Teneraca (Tepehuan village) (23°05'N, 104°45'W), in Arroyo de las Cuevas at streamside campsite locally known as Platanillos, 1600 m elev. 24 November 1970. Robert G. Webb. UTEP 11946. Verified by Roger Conant. Found in a clear-water stream surrounded by subtropical vegetation. New record for Durango, and located about 500 air km SE of the nearest records from southwestern Chihuahua in the vicinity of Río San Miguel-Río Verde (Tanner 1985. Great Basin Nat. 45:615–676). Color photographs of this snake, both captioned "Durango," appear on Plate 8 in Rossman et al. (1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman Oklahoma. xx + 332 pp.), but its occurrence in Durango was not otherwise indicated in their text or maps.

Submitted by **ROBERT G. WEBB**, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA; e-mail: rgwebb@utep.edu.

TRIMORPHODON BISCUTATUS (Lyre Snake). USA: NEW MEXICO: GRANT CO: Burro Mountains; Saddle Rock Canyon; N32°47.363', W108°30.181'. Juvenile. 15 November 2000. Eric M. Brand. University of New Mexico Museum of Southwestern Biology (MSB 62811). Verified by Charles W. Painter. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, xix + 431 pp.). Fills a large gap in range records from surrounding counties in New Mexico (Hildago, Luna, Sierra, Catron).

Submitted by **DON S. SIAS**, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA, and **ERIC M. BRAND**, 11 UT Drive, Silver City, New Mexico 88061, USA.

New Distribution Records of Reptiles from Western Venezuela

ALLAN L. MARKEZICH
Department of Natural Sciences & Engineering
Black Hawk College, 6600 34th Avenue, Moline, Illinois 61265-5899, USA
e-mail: markezicha@bhc1.bhc.edu

The composition and geographic distribution of the herpetofauna of the central portion of western Venezuela is poorly understood primarily because of the limited amount of previous work there. This area is ecologically and physiographically diverse, including several Andean ecosystems at various elevations bordered by a relatively flat upper llanos system to the east of these (Reaud-Thomas 1989). The distributions of many Venezuelan reptilian species depicted in commonly used references (e.g., Roze 1966)

often exhibit gaps or other anomalies in this region, and only sparse and scattered records exist in the literature. This situation clearly precludes assessments of herpetofaunal species richness, diversity indices, percentage endemism, and other ecological parameters that are often important and relevant to current conservation and preservation efforts. The Andean area of western Venezuela has been shown to be very important with respect to the total diversity (i.e., species richness) of mammals and birds in Venezuela (Rodríguez and Rojas-Suárez 1996) but the inadequate knowledge of the this area's herpetofauna does not yet permit such conclusions about its contribution to the herpetofaunal diversity of Venezuela.

I have investigated various aspects of the west central Venezuelan herpetofauna in the field and in museum collections since 1990. This paper reports new regional records, new state records, and geographic range extensions for 44 species of reptiles (29 snakes, 13 lizards, and 2 amphisbaenians), mainly from llanos and piedmont physiographic areas in the state of Portuguesa and adjacent states of Barinas, Lara, and Trujillo. Previous geographic records of species were established by reference to works that document specimens from specific localities and/or from works involving comprehensive local checklists. I have refrained from referring to works that show only stippling or shading on distribution maps to represent a species range since the depicted range usually represents an inductive hypothesis (Tucker 1995) if not based upon evidence from specific records. Many recent works that document regional geographic distributions of reptiles and amphibians (e.g., Phillips et al. 1999) take the empirical approach used in the present paper.

The scant previous herpetological research in west central Venezuela is evident from the absence of specimens from this region in most museum collections. Over the years however, I have had the opportunity to examine the herpetological collection at the Museo de Ciencias Naturales (MCNG), Guanare, Estado Portuguesa, Venezuela. This museum is on the campus of the Universidad Nacional Experimental de los Llanos Occidentales Ezequiel Zamora (UNELLEZ; coordinates 9°03'50"N, 69°48'30"W), which is a few kilometers from the west/northwestern edge of Guanare, the capital of the state of Portuguesa. It has a modest and well-curated herpetological collection containing specimens that have been collected primarily in the state of Portuguesa and secondarily in adjacent states since 1979. It also has specimens collected on various expeditions to other areas in Venezuela and type specimens from recently described species (e.g., Markezich and Taphorn 1994). All of the specimens reported upon in this paper are housed in this collection.

In this paper, subspecific names are used only if there has been a recent comprehensive variational study of the species (e.g., *Chironius carinatus* by Dixon et al. 1993), and taxa of uncertain affinity, several of which are currently under investigation by the author and others, have been omitted. Only one specimen of a conspecific series is listed from one locality, and separate localities within a state are reported if they represent significantly different geographic, physiographic, and/or ecological areas. Geographic coordinates have not been inferred from locality data, and are given only where directly recorded. Distances via roads are designated as such in this paper, and other distances between two points are linear. For brevity, I have used the abbreviation "Edo." for the phrase "the state of" in many cases. For ease of reference, the following information and coordinates are for two localities near Guanare that frequently appear in the list of species but may be difficult to locate on some maps: La Colonia (9°03'19"N, 69°48'58"W), 3 km westnorthwest of northwestern edge of Guanare; Mesa de Cavacas (cited as "Mesa Cavaca" on some maps; 9°04'22"N, 69°48'42"W), 7 km north of northwestern edge of Guanare on the road to Biscucuy. I have also refrained from comments pertaining to variation and taxonomy of the specimens reported upon in this paper, except in one case, and have examined all of the listed specimens.

Anomalepidae

Liotyphlops albirostris. PORTUGUESA: Municipio Guanare: Guanare. 31 May 1979. No collector listed in catalogue. Verified by J. R. Dixon. MCNG 836. First record from Portuguesa, ca. 170 km ENE of nearest record from Mérida, Edo. Mérida, where the only other specimens in west central Venezuela are known (Dixon and Kofron 1983).

Boidae

Boa constrictor. BARINAS: Municipio Bolivar: Rancho Luna, Barinitas. 30 June 1981. D. Gonzalez. MCNG 540; PORTUGUESA: Municipio San Genaro de Boconoito: San Nicolás. 13 November 1983. B. Busto and C. Ramo. MCNG 716. All specimens verified by T. Horger. First record from Barinas and range extension of 80 km S of nearest record from Aparición in Portuguesa (Roze 1966).

Corallus ruschenbergerii. PORTUGUESA: Municipio Guanare: La Colonia. 20 July 1983. S. Reid. Verified by D.C. Taphorn. MCNG 732. First record from Portuguesa, ca. 160 km WNW of record from Edo. Barinas (Henderson 1997).

Epicrates cenchria. BARINAS: Municipio Rojas: Hato San Pancracio, Santa Rosa. 28 May 1981. B. Busto and C. Ramo. MCNG 495; PORTUGUESA: Municipio Papelón: 20–40 km (road) SE Guanare on Guanare-Guanarito Rd. 8 July 1993, 2100–2300 h. A. L. Markezich and O. J. León. MCNG 1480. All specimens verified by T. Horger. First records from Barinas and Portuguesa, extending range ca. 200 km E of the first records from west central Venezuela in Edo. Mérida (La Marca and Soriano 1995; Roze 1966).

Colubridae

Atractus univittatus. PORTUGUESA: Municipio Guanare: La Colonia. 11 December 1990. D. C. Taphorn. MCNG 1239; Municipio Guanare: 12 km (road) S Rio Guanare bridge on Guanare-Biscucuy Rd. 7 July 1993. A. L. Markezich and O. J. León. MCNG 1479. Both specimens verified by J. R. Dixon. First records from western Venezuela. This species was previously known only from the holotype from the Caracas region and one specimen from Estado Miranda, ca. 400 km NW of the records reported here. The two MCNG specimens recorded above and two others in MCNG from the same area in Portuguesa match the original description of Jan (1862) and that given by Roze (1966) in most details of scalation and color pattern of this species. However, there is an inconsistency in reported infralabial number in the literature. The figured type specimen of Jan (1862, 11th Livr., PL. II) and the specimens from Portuguesa have seven infralabials while Roze (1966) and other general references have cited six for this species apparently

based upon the specimen from Edo. Miranda that he examined. Thus the species should be considered to have 6–7 infralabials, a common range of variation in this character in colubrids. The temporal number of 2+2 figured and cited by Jan (1862) for the holotype was also a variant, as the specimen examined by Roze (1966) and the series examined here from Portuguesa have 1+2 temporals. Thus, this species should be considered to have 1+2 or 2+2 temporals.

Chironius carinatus spixi. PORTUGUESA: Municipio Guanare: UNELLEZ campus. 21 November 1990, 0900 h. A. L. Markezich. MCNG 1251; Municipio San Genaro de Boconoito: San Nicolás. 16 August 1981. G. Rios. MCNG 538; Municipio undetermined: carretera Guanare-Guanarito. 19 October 1980. B. Busto and C. Ramo. MCNG 105. All specimens verified by T. Horger. Dixon et al. (1993) reported several specimens from the northern part of this state near Acarigua, and another was recently reported from Biscucuy in the northwestern piedmont of the state (Esqueda and La Marca 1999). The specimens reported here extend the range 75 km from these records and document the existence of this species in central and southwestern Portuguesa.

Dipsas variegata. PORTUGUESA: Municipio Monseñor José Vicente de Unda: Chabasquen, Cerro Mollejon. 30 September 1983. B. Busto and C. Ramo. Verified by P. Pacheco. MCNG 787. First record from western Venezuela, ca. 350 km WSW of nearest known records from Distrito Federal (Roze 1966).

Erythrolamprus bizonus. BARINAS: Municipio Antonio Jose de Sucre: Socopo. 22 March 1981. M. Soto. Verified by P. Pacheco. MCNG 943; PORTUGUESA: Municipio Guanare: UNELLEZ, Mesa de Cavacas. 6 August 1984. B. Busto and C. Ramo. Verified by P. Pacheco. MCNG 866; Municipio Guanare: Guanare, Jardin "Centro de Bellas Artes." 29 October 1986. R. Zapata. Verified by P. Pacheco. MCNG 942; TRUJILLO: Municipio Boconó: 28 km (road) SW Campo Elías on road to Boconó, 9°18'16"N, 70°10'03"W, 1580 m elev. 27 May 1998, 1100 h. A. L. Markezich and O. J. León. Verified by T. Horger. MCNG 1601. First records from Barinas and Portuguesa, filling the middle of a previous range gap of ca. 500 km from north central Venezuela to Edo.Táchira in southwestern Venezuela (Roze 1966).

Helicops angulatus. PORTUGUESA: Municipio Papelón: 40 km (road) SE Guanare on Guanare-Guanarito Rd. 10 July 1993, 1030 h. A. L. Markezich and O. J. León. MCNG 1498. First record of this locally common species from Portuguesa and only record of this species in western Venezuela other than those cited by Roze (1966) from Edo. Zulia, ca. 300 km west. The nearest llanos record is from Edo. Apure, ca. 230 km SE of the Portuguesa locality reported here (Staton and Dixon 1977).

Helicops pastazae. BARINAS: Municipio Ezequiel Zamora: upper reaches of Rio Caparo. 13 February 1983. B. Busto and C. Ramo. Verified by D. A. Rossman. MCNG 737. New record from Barinas. Markezich and Rossman (1992) incorrectly reported the locality of this specimen as being in Edo. Portuguesa due to an error in the MCNG catalogue. The locality in Barinas is ca. 130 km NE of the only other known record of this species in west central Venezuela cited by these authors from Edo. Táchira.

Imantodes cenchoa. PORTUGUESA: Municipio Papelón: 24 km (road) SE Guanare on Guanare-Guanarito Rd. 9 July 1993, 2350 h. A. L. Markezich and O. J. León. Verified by P. Pacheco. MCNG 1489. Second record from west central Venezuela, ca. 200 km ENE of nearest record from Edo. Mérida (Esqueda and La Marca 1999).

Leptodeira annulata ashmeadi. BARINAS: Municipio Barinas: Barinas. 29 January 1980. E. La Marca and G. Carrillo. MCNG 437; Municipio Rojas: Hato San Pancracio, Sta. Rosa. 31 December 1982. B. Busto and C. Ramo. MCNG 547; PORTUGUESA: Municipio Guanare: La Colonia. 13 July 1993. D. C. Taphorn. MCNG 1503; Municipio Guanarito: Palmar de Morrones, Guanarito. 30 September 1981. Busto and C. Ramo. MCNG 427; Municipio San Genaro de Boconoito: represa de Tucupido. 12 May 1989. M. Guttiererez. MCNG 1083; Municipio San Rafael de Onoto: San Rafael de Onoto. 12 May 1984. MCNG 1255; Municipio undetermined: 20–40 km (road) SE Guanare on Guanare-Guanarito Rd. 8 July 1993, 2200 h. A. L. Markezich and O. J. León. MCNG 1483. All specimens verified by P. Pacheco. First records of this common species from Barinas and Portuguesa, with most distant Portuguesa and Barinas records ca. 250 km ENE and 180 km E, respectively, of nearest record from Edo. Mérida (Duellman 1958; Roze 1966).

Leptophis ahaetulla. PORTUGUESA: Municipio Guanare: Guanare, carrera 6 frente a Malariologia. 8 May 1987, 0900 h. J. V. Paez. MCNG 990; Municipio Monseñor José Vicente de Unda: Chabasquen. 5 November 1983. B. Busto and C. Ramo. MCNG 729. Both specimens verified by P. Pacheco. First records from Portuguesa, ca. 180 km SSW of nearest record from Edo. Yaracuy (Roze 1966).

Liophis lineatus. PORTUGUESA: Municipio Guanare: La Colonia. 19 December 1990. D.C. Taphorn and L. M. Page. MCNG 1250; Municipio Guanarito: N of Guanarito, 5.3 km (road) E of Guanare-Guanarito Rd. on road to La Trinidad, 8°43'33"N, 69°11'44"W, 50 m elev. 1 May 1998. A. L. Markezich and O. J. León. Verified by T. Horger. MCNG 1609. Known from Acarigua in northern Portuguesa (Roze 1966), these specimens extend the range 80 km SW and 100 km S in this state. Records from Portuguesa are apparently rare, as Michaud and Dixon (1987) did not include specimens from this state in their recent comprehensive revision of this species.

Liophis melanotus melanotus. PORTUGUESA: Municipio Sucre: 4 km (road) N Las Guafas, 21 November 1990, 1500 h. A. L. Markezich and O. J. León. MCNG 1608; Municipio Guanare: Guanare. 17 November 1983. B. Busto and C. Ramo. All specimens verified by T. Horger. Localities are 75 km SW and SSW of documented specimens from the Acarigua area of northern Portuguesa (Dixon and Michaud 1992).

Mastigodryas bifossatus. BARINAS: Municipio Rojas: Hato San Pancracio, Santa Rosa. 31 December 1982. B. Busto and C. Ramo. MCNG 545; PORTUGUESA: Municipio Guanare: 15 km E Guanare, Finca Robalito. 29 November 1990. C. Lileystron. Verified by P. Pacheco. MCNG 467; Municipio Guanare: La Colonia. 29 July 1991. D. C. Taphorn. MCNG 1388. All specimens verified by P. Pacheco. First records from west central Venezuela, representing the westernmost records in Venezuela, ca. 250 km WSW and W of nearest records from Edo. Guárico (Roze 1966).

Ninia atrata. PORTUGUESA: Municipio Guanare: UNELLEZ campus, Mesa de Cavacas. February 21, 1984. A. Garcia. Verified by

P. Pacheco; MCNG 740. First record from Portuguesa, filling the middle of a significant range gap of ca. 500 km from north central Venezuela to Edo. Táchira in southwestern Venezuela (Roze 1966).

Oxyrhopus petola. PORTUGUESA: Municipio Guanare: La Colonia. 23 October 1983. MCNG 767; Municipio Monseñor José Vicente de Unda: Chabasquen, Cerro Mollejon. 20 May 1983. B. Busto and C. Ramo. MCNG 765; Municipio Papelón: 27 km (road) SE Guanare on Guanare-Guanarito Rd. 9 July 1993, 2300 h. A. L. Markezich and O. J. León. MCNG 1486. All specimens verified by P. Pacheco. First records from Portuguesa extending range ca. 200–225 km NE and E of first record from west central Venezuela in Edo. Mérida (Esqueda and La Marca 1999; Roze 1966).

Pseudoboa neuwiedii. PORTUGUESA: Municipio Guanare: UNELLEZ campus, pabellon "E." 11 February 1991. O. J. León. MCNG 1328; Municipio Papelón: 22 km (road) SE Guanare on Guanare-Guanarito Rd. 13 July 1993, 2130 h. A. L. Markezich and O. J. León. MCNG 1504. All specimens verified by T. Horger. First records from Edo. Portuguesa, ca. 150 km SW of nearest record from Edo. Yaracuy (Roze 1966).

Sibon nebulata. BARINAS: Municipio Rojas: Hato San Pancracio, Sta. Rosa. 17 August 1980. B. Bockma and C. Ramo. MCNG 67; PORTUGUESA: Municipio Monseñor José Vicente de Unda: Cerro Mollejon, Chabasquen. 25 March 1983. B. Busto and C. Ramo. MCNG 784; Municipio Papelón: 26 km (road) SE Guanare on Guanare-Guanarito Rd. 10 July 1993, 2030 h. A. L. Markezich and O. J. León. MCNG 1496. All specimens verified by P. Pacheco. Roze (1966) reported the nearest record from Agua Blanca near the northernmost tip of Portuguesa. The specimens represent a new state record from Barinas, ca. 150 km S of Agua Blanca, and range extensions in Portuguesa of 80 km WSW and 90 km SSW of Agua Blanca.

Spilotes pullatus. BARINAS: Municipio Rojas: Hato San Pancracia, Sta. Rosa. 31 May 1981. B. Busto and C. Ramo. MCNG 546; PORTUGUESA: Municipio Guanare: La Colonia. 27 April 1980. B. Busto and C. Ramo. MCNG 775; Municipio Ospino: 7.8 km (road) N Estación, 9°25'01"N, 69°32'55"W, 960 m elevation. 26 May 1998. A. L. Markezich. MCNG 2004; Municipio undetermined: carretera Guanare-Guanarito. 3 September 1980. B. Bockma and C. Ramo. MCNG 89. All specimens verified by T. Horger. First record from these states, ca. 120–180 km E of nearest records from Edos. Mérida and Trujillo (Roze 1966; La Marca and Soriano 2000).

Tantilla melanocephala. PORTUGUESA: Municipio Guanare: UNELLEZ campus, Mesa de Cavacas. 16 June 1981. C. Briceno. Verified by P. Pacheco. MCNG 831; Municipio Sucre: 22 km (road) N Mesa de Cavacas. 23 July 1991, 2200 h. A. L. Markezich and O. J. León. Verified by T. Horger. MCNG 1603. This is only the second report of this species in west central Venezuela, ca. 170 km ENE of nearest record from Edo. Mérida (Wilson and Mena 1980).

Elapidae

Micrurus isozonus. PORTUGUESA: Municipio Guanare: UNELLEZ campus. 28 November 1983. B. Busto and C. Ramo. Verified by D.C. Taphorn. MCNG 725; Municipio Ospino: Esparanza, 10.6 km (road) N of intersection with road to Estación, 9°27'27"N, 69°30'49"W, 780 m elev. 10 May 1998, 0900 h. Verified by T. Horger. A. L. Markezich and O. J. León. MCNG 1610. These specimens extend the range of this species in Portuguesa ca. 65 km SSW of nearest known record from Aparición (Roze 1966).

Micrurus mipartitus. PORTUGUESA: Municipio Monseñor José Vicente de Unda: Chabasquen, Cerro Mollejon. 30 November1983. B. Busto and C. Ramo. Verified by P. Pacheco. MCNG 776; Municipio Sucre: Biscucuy. 1989. A. Mejias. Verified by T. Horger. MCNG 1344. First records from Portuguesa filling a range gap of ca. 300 km between previous records from Edo. Yaracuy and Edo. Mérida (Roze 1966, 1996).

Leptotyphlopidae

Leptotyphlops albifrons. LARA: Municipio Iribarren: Barquisimeto. 31 March 1979. B. Bockma. MCNG 834; PORTUGUESA: Municipio Guanare: Guanare. 31 May 1979. No collector listed in catalogue. MCNG 833. Both specimens verified by J. R. Dixon. First record from west central Venezuela, ca. 250 km SSW of nearest record from Edo. Falcón (Roze 1966).

Leptotyphlops macroplepis. PORTUGUESA: Municipio Guanare: Mesa de Cavacas. 9 September 1990. J. L. Atuve. Verified by J. R. Dixon. MCNG 1124. This specimen extends the range of this species in Portuguesa 65 km SSW of the nearest record from Aparición in this state (Roze 1966).

Typhlopidae

Typhlops reticulatus. BARINAS: Municipio Antonio Jose de Sucre: Socopo. 22 March 1981. E. La Marca. MCNG 943. Verified by P. Pacheco; PORTUGUESA: Municipio Papelón: 5 km (road) SE Papelón, Finca Palma Sola, 8°42'18"N, 69°13'02"W, 70 m elev. 28 April 1998. O. Castillo. Verified by T.H. Horger. MCNG 1604. First record from Barinas and a range extension of 80 km S of a recently reported specimen from Acarigua in Portuguesa (Rivas et al. 2001). This species has seldom been recorded from Venezuela, and these specimens represent the second and third ones from the upper llanos of western Venezuela (Dixon and Hendricks 1979).

Viperidae

Bothrops venezuelensis. PORTUGUESA: Municipio Monseñor José Vicente de Unda: Chabasquen, Cerro Mollejon. 29 February 1984. B. Busto and C. Ramo. Verified by P. Pacheco. MCNG 874. First record from Portuguesa. Campbell and Lamar (1989) pointed out conflicts in the literature with respect to the geographic distribution of this species and listed several states in Venezuela from which it is reliably known including Lara, adjacent to Portuguesa, without mentioning specific localities. A specific record from Lara was recently reported (Esqueda and La Marca 1999) from a locality ca. 30 km NE of the specimen from Portuguesa recorded here.

Crotalus durissus. PORTUGUESA: Municipio Guanarito: Palmar de Morrones. 31 January 1983. B. Busto and C. Ramo. Verified by P. Pacheco. MCNG 735. First record from Portuguesa ca. 150 km SW of nearest record from Edo. Trujillo (Roze 1966).

Gekkonidae

Gonatodes vittatus. PORTUGUESA: Municipio Monseñor José Vicente de Unda: Paraiso de Chabasquen, 9°25'56"N, 69°56'48"W, elevation 590 m. 22 April 1998, 1530 h. A. L. Markezich. Verified by T. Horger. MCNG 1605. First record from Portuguesa, ca. 125 km

NE of records from Edo. Mérida (Rivero-Blanco 1979).

Hemidactylus palaichthus. BARINAS: Municipio Bolivar: Barinitas, 8°45'21"N, 70°24'48"W, 440 m. 18 May 1998, 1030–1200 h. A. L. Markezich and O. J. León. Verified by T. Horger. MCNG 1613; PORTUGUESA: Municipio Guanare: Barrio La Arenosa, Guanare. 19 June 1981. H. Cuevas. Verified by A. Bauer and T. Russell. MCNG 417; Municipio Guanarito: Palmar de Morrones. 21 November 1983. B. Busto and C. Ramo. Verified by A. Bauer and T. Russell. MCNG 676. First records from west central Venezuela, ca. 150 km WNW and 130 km NNW of nearest records from near Bruzual, Edo. Apure (Staton and Dixon 1977).

Phyllodactylus ventralis. PORTUGUESA: Municipio Guanare: La Colonia, 9°03'19"N, 69°48'58"W. 2 November 1987. D.C. Taphorn. MCNG 1127; Municipio Guanare: Guanare. 19 July 1983. B. Busto and C. Ramo. MCNG 674; Municipio San Genaro de Boconoito: represa del Rio Boconó. 22 November 1982. B. Busto and C. Ramo. MCNG 401. All specimens verified by P. Pacheco. These specimens extend the range 50–80 km SW of nearest records from the Acarigua and Aparición areas of northern Portuguesa (Dixon and Huey 1970).

Iguanidae

Iguana iguana. PORTUGUESA: Municipio Guanarito: Guanarito. 6 July 1980. B. Bockma and C. Ramos. MCNG 48; Municipio Guanare: Guanare, Barrio Colombia, 26 June 1983. Y. Hernandes. MCNG 442. All specimens verified by P. Pacheco. While it is generally recognized that this species occurs in much of Venezuela, documented records are scarce (Avila-Peres 1995). This is apparently the first record of it from west central Venezuela, 130 km NNW of records near Bruzual, Edo. Apure (Staton and Dixon 1977).

Polychrotidae

Anolis auratus. PORTUGUESA: Municipio Guanare: Guanare, Urb. Hato Modelo. 17 March 1980. B. Bockma and C. Ramo. MCNG 22; Municipio Guanare: UNELLEZ, Mesa de Cavacas. 6 September 1983. B. Bockma and C. Ramo MCNG 853. All specimens verified by E. E. Williams. First records from Portuguesa, 80 km S of nearest record from Edo. Barinas (Avila-Peres 1995; Donoso-Barros 1968).

Anolis nitens nitens. PORTUGUESA: Municipio Guanare: Mesa de Cavacas. 22 April 1980. MCNG 802; Municipio San Genaro de Boconoito: Rio Tucupido, arriba represa. 8 April 1983. MCNG 800. Both specimens collected by B. Busto and C. Ramo and verified by E. E. Williams. First records from Portuguesa, ca. 200 km SW of nearest records from Edo. Yaracuy (Vanzolini and Williams 1970).

Polychrus marmoratus. PORTUGUESA: Municipio Guanare: UNELLEZ campus. 20 June 1991. M. Gonzalez. Verified by P. Pacheco. MCNG 1357. First record from west central Venezuela, ca. 250 km SE of nearest record from Edo. Carabobo (Avila-Peres 1995).

Tropiduridae

Tropidurus hispidus. BARINAS: Municipio Rojas: Hato San Pancracia, Sta. Rosa. 27 November 1983. B. Busto and C. Ramo. MCNG 651; PORTUGUESA: Municipio Guanare: Fundo Sabana Grande, Tucupido. 26 June 1983. B. Busto and C. Ramo. MCNG 649; Municipio Guanare: Guanare. 15 May 1982. C. A. Rodriguez. MCNG 647; Municipio Guanarito: El Palmar de Morrones, Guanarito. 21 November 1983. MCNG 657. All specimens verified by P. Pacheco. First records from Portuguesa. The Portuguesa records are 80 km NNE and the Barinas records 80 km E of nearest record from Barinas in Edo. Barinas (Avila-Peres 1995; Donoso-Barros 1968).

Teiidae

Ameiva ameiva. PORTUGUESA: Municipio Guanare: Fundo Sabana Grande, Tucupido. 26 June 1983. MCNG 620; Municipio Guanare: La Colonia. 17 June 1984. MCNG 793; Municipio Guanarito: Guanarito. 21 November 1983. MCNG 588. All specimens collected by B. Busto and C. Ramo and verified by P. Pacheco. First records from Portuguesa, ca. 80 km NNE of nearest record from Barinas in Edo. Barinas (Avila-Peres 1995; Donoso-Barros 1968).

Cnemidophorus gramivagus. BARINAS: Municipio Sosa: Puerto de Nutrias, just E of lower portion of Rio Apure bridge. 22 June 1996, 1800–1900 h. A. L. Markezich and O. J. León. Verified by C. J. Cole. MCNG 1606; PORTUGUESA: Municipio Guanare: Urb. Fundaguanare, Guanare. 23 April 1981. C. Briceno. Verified by T. Horger. MCNG 328; Municipio Guanarito: 9.7 km (road) SW Guanarito. 21 June 1996, 1800–1900 h. A. L. Markezich and O. J. León. Verified by C. J. Cole. MCNG 1607. First records from Barinas and Portuguesa and previously known only from Edo. Apure in Venezuela. These specimens extend the range ca. 150 km NNW of nearest Apure record (McCrystal and Dixon 1987).

Tupinambis teguixin. PORTUGUESA: Municipio Guanare: La Colonia. 17 June 1984. B. Busto and C. Ramo. Verified by P. Pacheco. MCNG 796. First record of this species from Portuguesa, ca. 130 km NNW of nearest record from Edo. Barinas (Donoso-Barros 1968).

Gymnophthalmidae

Bachia heteropa lineata. PORTUGUESA: Municipio San Genaro de Boconoito: Rio Tucupido, arriba represa. 2 February 1983. B. Busto and C. Ramo. Verified by J. R. Dixon. MCNG 750. First record from Portuguesa, extending the range (distance undetermined) N of record from western Edo. Barinas (Dixon 1973).

Gymnophthalmus speciosus. PORTUGUESA: Municipio Guanare: La Colonia. 19 December 1990. A. L. Markezich and D. C. Taphorn. Verified by C. J. Cole. MCNG 1249; UNELLEZ campus. 18 March 1985. R. Thourex. Verified by P. Pacheco. MCNG 1316. Specimens extend range 90 km S of nearest record from the Acarigua area of Portuguesa (Cole et al. 1990).

Amphisbaenidae

Amphisbaena alba. BARINAS: Municipio Ezequiel Zamora: Pedraza. 25 April 1981. E. La Marca. MCNG 860; LARA: Municipio Urdaneta: 12 km (road) W Santa Inés. 27 November 1990. A. L. Markezich. MCNG 1128; PORTUGUESA: Municipio Guanare: Colonia. 21 November 1990. A. L. Markezich. MCNG 1115; Municipio Sucre: Biscucuy. 20 August 1983. B. Busto and C. Ramo. MCNG 553. All specimens verified by P. Pacheco and D. C. Taphorn. First records from these three states in west central Venezuela representing distances of ca. 225 km SSW, 150 km NE, and 80 km SE of nearest record from Edo. Trujillo in this region

(Donoso-Barros 1968; Esqueda and La Marca 1999; Gans 1962). *Amphisbaena fulginosa*. PORTUGUESA: Municipio Sucre: 4 km (road) N Las Guafas on Guanare-Biscucuy Rd. 21 November 1990, 1500 h. A. L. Markezich and O. J. León. Verified by D. C. Taphorn. MCNG 1116. First record of this species in west central Venezuela, ca. 250 km SE of nearest records from Edo. Falcón (Donoso-Barros 1968; Vanzolini 1951).

Acknowledgments.—I am grateful to my colleagues and friends at UNELLEZ and MCNG—Donald C. Taphorn, Pedro Pacheco, and Juan Elías García-Pérez—for furnishing museum resources and many other kinds of assistance during the course of my studies there. Special thanks go to Oscar León of UNELLEZ for his reliable and cheerful assistance with critical fieldwork for many years, often for long periods of time under demanding conditions. Tim Horger of Illinois Valley Community College also provided much-needed help with fieldwork. I also thank all those mentioned in this paper who verified specimen identifications, as well as Alan Resetar (Field Museum of Natural History, Chicago) and Jose Rosado (Museum of Comparative Zoology, Harvard University) for various types of help. I appreciate the support and patience of my family, Madelynn and Matthew, during this project. The extensive collecting efforts in the 1980's of B. Busto and C. Ramo, two people whom I have never met and formerly of UNELLEZ and MCNG, contributed significantly to our knowledge of the herpetofauna of west central Venezuela. Fieldwork was made possible by the PROFAUNA division of the Venezuelan Ministerio del Ambiente y de los Recursos Naturales Renovables (MARNR), Caracas, who kindly issued collecting permits over the years. This project was funded in part by the National Geographic Society (grant 6176-98) to the author.

e-mail (JHT): joetownsend@earthlink.net

Florida is well known for its non–native herpetofauna (King and Krakauer 1966; Wilson and Porras 1983). The substantial trade in exotic plants and animals and the humid subtropical environment in Florida have been instrumental in perpetuating populations of exotics.

From May 2000 through March 2001, we surveyed areas in Florida where introduced species have been reported and other areas that contained suitable habitat. We utilized a variety of diurnal capture methods including blowguns with corks, fishing rods with barbless hooks (Krysko 2000) and nooses (Strong et al. 1993). In nocturnal situations we searched areas around houses and buildings. Representative voucher specimens were deposited in the Florida Museum of Natural History (FLMNH), Gainesville, Florida. Additionally three new county records were kindly provided by the California Academy of Science (CAS). All of the following records were collected by the authors unless otherwise noted.

Anura

Osteopilus septentrionalis (Cuban Treefrog). HERNANDO Co: Brooksville, North Avenue. 21 June 1995. CAS 199808–10. Collected by P. G. Frank. First county record.

Testudines

Trachemys scripta elegans (Red-eared Slider). VOLUSIA Co: South Daytona, Reed Canal Park. 25 November 2000. UF 122517. These turtles are the most commonly observed species in area ponds and canals, and additional specimens of adults and juveniles were collected 17 March 2001 (UF 122784–6) and 24 June 2001 (UF 124767–8).

Lacertilia

Anolis cybotes (Largehead Anole). MIAMI-DADE Co: Key Biscayne, near the grounds of the old Crandon Park Zoo. 17 December 2000. UF 121416 and 121450. Previously only known from a limited area in northeastern Miami-Dade County (Ober 1973; Wilson and Porras 1983).

Anolis sagrei (Brown Anole). LEE Co: Gasparilla Island (26°42'371"N, 82°16'360"W). 21 December 2000. UF 121462–63. First record from Gasparilla Island. These lizards are common on Gasparilla Island and have likely been established there for some time. GILCHRIST Co: Fanning Springs, Rt. 19, across from entrance to Fanning Springs State Recreation Area. 3 March 2001. UF 122516. New county record. LEVY Co: Chiefland, 1285 Highway 19. 3 March 2001. UF 122515. New county record. MARTIN Co: Lake Okeechobee, jct. CR 71 and US 441. 2 March 2001. UF 122463. New county record. Found in Australian pine tree (*Casuarina equisetifolia*) stand. This record fills a gap in distributional records between St. Lucie and Palm Beach counties. *Anolis sagrei* has now been collected in all 12 Atlantic coastal counties. TAYLOR Co: Econfina River State Park (30°03'31.9"N, 83°54'23.8"W). 20 April 2000. CAS 214327. Collected by R. Lawson, P. G. Frank, N. Frank, and J. Frank. New county record.

Hemidactylus garnotii (Indo-pacific Gecko). CHARLOTTE Co: Gasparilla Island (26°47'677"N, 82°16'706"W). 21 December 2000. UF 121506. New county record. Found under bark of *Casuarina equisetifolia.*

Hemidactylus mabouia (Tropical Gecko). LEE Co: Gasparilla Island (26°42'371"N, 82°16'360"W). 21 December 2000. UF 121464 and 121468–502. New county record. Found in debris and under the bark of *Casuarina equisetifolia.*

Hemidactylus turcicus (Mediterranean Gecko). CITRUS Co: Inverness, Withlacoochee Walking Trail (28°50'16.9"N, 82°19'47.3"W). 2 October 1999. CAS 210987. Collected by R. Lawson, P. G. Frank. New county record.

Iguana iguana (Green Iguana). BROWARD Co: Davie, SW 76 Avenue, 0.4 mi S Griffin Road. 25 March 2001. UF 123126. Davie, Taft Street, 100 yards W of NW 85th Way. UF 123127. 25 March 2001. Both collected by S. B. Thompson. New county record.

Leiocephalus schreibersi (Red–sided Curlytail Lizard). BROWARD Co: Hollywood, 5920 Thomas Street. 16 December 2000. UF 121397–99. New county record.

Serpentes

Ramphotyphlops braminus (Brahminy Blind Snake). ALACHUA Co: Gainesville, 1700 SW 23rd Drive. 17 March 1998. (UF 111650). Collected by Calvin Teele. New county record. Collected from under debris at USDA Laboratory.

Acknowledgments.—We thank R. Lawson (CAS) for permission to use their records; J. N. Decker, R. H. Robins, A. Soleymani, S. B. Thompson, A. M. Roth, and C. Teele for help obtaining specimens in the field; C. M. Miskis and S. H. and T. B. Townsend for providing housing; M. A. Nickerson and S. A. "Picklebarrel" Johnson for helpful suggestions on this paper.

e-mail: ken_dodd@usgs.gov

The Great Smoky Mountains are an important center of herpetofaunal diversity, especially for amphibians. With more than 40 species of amphibians and 35 species of reptiles, Great Smoky Mountains National Park, the focus of this short, descriptive guide, is also the most visited national park in the United States. Through the years, the Great Smoky Mountains Natural History Association has produced a number of pocket-sized field guides (e.g., on birds and trees) which allow visitors to quickly identify the fauna and flora of the park. *Reptiles & Amphibians of the Smokies* is the latest in this series of guidebooks. The audience for which it is written is the casual visitor who has some interest in amphibians and reptiles, and may wish to identify animals observed during a visit to the park. It does not present detailed information on the natural history of the herpetofauna specifically pertaining to the park, such as contained in Huheey and Stupka's (1967) long outdated, but still very informative, book, and it does not purport to be a regional field guide.

The book is organized into basically two parts. The first part contains an introduction on how to use the book, sections on amphibian and reptile diversity within the park, notes on life histories and interesting facts about the biology of amphibians and reptiles, and several pages each on the ecological and geological settings of the Great Smokies and the need for the preservation of biodiversity. The style of writing and the information content is extremely basic, that is, for the non-biological public, and the authors have done a fine job of presenting information in a very readable and non-technical format. I found little to quibble with in this section, but there are a few inconsistencies.

The authors state that 12 anurans are found in the park on p. 21, but include 13 species accounts and use the figure 13 elsewhere in the book. Actually, both figures are correct in a sense. Whereas 13 species have been reported from the park, *Acris crepitans* probably never occurred within its boundaries despite its inclusion in previous checklists (e.g., Huheey and Stupka 1967). The authors use the spelling Pygmy in some places, but Pigmy (e.g., for the Pigmy Salamander) elsewhere. I would quibble with a few statements here and there, such as that Four-toed Salamanders are uncommon "even where they do occur;" actually, this species can be found in good numbers at certain times of the year and at specific localities. Such minor criticisms are few, however, and do not detract from the book's purpose to inform the general public.

The second part of the book (84 pp) is composed of species accounts: 30 salamanders, 13 frogs, 7 turtles (plus one miscellaneous "other turtles" account), 8 lizards (*Eumeces fasciatus* and *E. inexpectatus* are treated in a single account), and 23 snakes. Although the Green Salamander (*Aneides aeneus*) is known historically from the park, its status is discussed only in the introduction and not in a specific species account. One page is devoted to each account, and about half the page consists of a beautiful full-color photograph. Although not stated explicitly, the animals photographed did not necessarily originate from the park, as the authors used generic photos at least for the rare or recently discovered species. The remainder of the account consists of the briefest of descriptions, information on habitat and life history, and similar species. Space limitations preclude much detail, but the general information provided probably is enough for a casual park visitor.

After conducting intensive surveys in the Great Smokies during the last four years, I can find a number of statements in the species accounts with which I disagree. For example, Hellbenders have been found in Deep Creek and Oconaluftee River, despite the authors' assertion that there are no recent records outside of Little River; Eastern Painted Turtles no longer occur in Gum Swamp (no sightings in four years or more, despite intensive surveys); Northern Map Turtles occur at least to the vicinity of the Abrams Creek Ranger Station, not just near the mouth of Abrams Creek; the Mud Salamander in the park is clearly not the Midland Mud Salamander (*Pseudotriton montanus diastictus*). What really disturbs me, however, are the data presented for the first time without attribution: the first report of Stinkpots from the park (although there are no specimens or photographs of the actual turtle found); the data on current distribution of Seepage and Junaluska Salamanders; the sighting at Abrams Creek of *Rana sphenocephala* in 2000. This information was collected by U.S.G.S. survey crews, not the authors, and is contained in reports to the park. Although public information, it would have been nice to acknowledge the source, and the potential biases, of the data. As it stands, a reader is left with the impression that the information results solely from the authors' observations. New records or sightings of species thought extirpated from public lands should be properly reported in the published, including popular, literature only when accompanied by specimens or unequivocal photographs.

Despite these criticisms, the book fulfills the goals of the Great Smoky Mountains Natural History Association to provide the layman with a generally high-quality and technically accurate overview of the amphibians and reptiles of the Great Smoky Mountains National Park. The color plates, in particular, are certain to pique interest and appreciation of the diverse herpetofauna. The

price is reasonable. However, professional biologists should delve deeper into the origin of distributional and life history information relating to the amphibians and reptiles of the park, and verify the accuracy of records and observations. What really is needed for the Smokies, and indeed for all major national parks, is a field guide of the quality of Koch and Peterson's (1995) guide to the amphibians and reptiles of Yellowstone and Grand Tetons national parks.

Amphibians and Reptiles of Pennsylvania and the Northeast, by Arthur C. Hulse, C. J. McCoy, and Ellen J. Censky. 2001. Cornell University Press, Ithaca, New York. xi + 419 pp, Hardcover, US $39.95. ISBN 0-8014-3768-7.

JOHN J. MORIARTY
Ramsey County Parks, 2015 North Van Dyke Street
Maplewood, Minnesota 55109, USA
e-mail: john.moriarty@co.ramsey.mn.us

Amphibians and Reptiles of Pennsylvania and the Northeast is the first complete treatment of the amphibians and reptiles in the state. McCoy (1982) provided excellent maps, and a bibliography, but did not report on the ecology, natural history and conservation. The classic accounts by Surface (1906, 1907, 1908, 1913) did not include all the species and were limited to the knowledge of the day.

This book covers the 76 species found in Pennsylvania, plus nine additional species found in other northeastern states. A checklist of the species by state is not included. This would be a helpful tool. The one group not covered, or even mentioned, is the sea turtles. Sea turtles are covered in recent works on Connecticut (Klemens 1993), Maine (Hunter et al. 1999), and New York (Breisch et al. 1998).

Amphibians and Reptiles of Pennsylvania and the Northeast consists of an introduction, amphibian accounts, reptile accounts, and appendices. The Introduction includes good information on the landforms, climate, and vegetation of Pennsylvania. Information on the other northeastern states is general, and lacks the detail provided for Pennsylvania. There are numerous times when the authors mention a particular county in the state to highlight their description. Unfortunately, there is NO map of the state showing the names of the counties. This oversight makes it difficult to follow the information in the introduction and throughout the book. A map placed on the inside front cover would be a nice addition when this book is reprinted.

Species accounts include a Description, Confusing Species, Habitat and Habits, Reproduction, Remarks, and Distribution, along with a map, and are complete for most species. However, the section headings are in the same font and style as the text, making it difficult to quickly locate specific information.

I found the Distribution section troubling, in part because of the absence of a state map for reference. The range maps were a disappointment, as they cover the northeastern states only with a general indication of range, largely derived from the maps of Conant and Collins (1991). However, the maps for Pennsylvania show county lines and contain point locality data of several types. Unfortunately, the Pennsylvania map is so small it is hard to make out the symbols. I would have preferred a larger Pennsylvania map, as this is the main area of the book, with a smaller inset map depicting the northeast region.

Moreover, the maps for areas outside of Pennsylvania could have been rendered more accurate if the authors had consulted various state and regional works. For several species, the ranges depicted are much larger than known distributions (e.g., Eastern Spadefoot, Eastern Box Turtle, Red-bellied Snake, Timber Rattlesnake).

A highlight of many of the newer state works has been the inclusion of high quality photographs. One of the best is *The Amphibians and Reptiles of Missouri* (Johnson 2000), in which the photos are positioned with the species accounts. I realize that it is more expensive to place the photos throughout the book, rather than in one signature, but it makes for a more user-friendly book. There are many nice photos in this book, but unfortunately there are just as many that are too small. Two examples are photos 3 and 33, which if properly cropped would be more effective. Although I was pleased to see photographs of salamander larvae, those for tadpoles were missing.

The only species account that fell short of the mark was that for the gray treefrogs (*Hyla chrysoscelis* and *H. versicolor*), combined into a single account, despite different habitat requirements and behaviors (Oldfield and Moriarty 1994; Vogt 1981). *Hyla chrysoscelis* is restricted to the southern edge of Pennsylvania and not found in any of the New England states or New York (Breisch 1998; Hunter et al. 1999; Klemens 1993; Cline, *in press*; Taylor 1993), while *H. versicolor* is the dominant species in these areas. These species should have separate accounts as was done for *Ambystoma laterale* and *A. jeffersonianum*.

The Mensural and Reproductive Data tables should have been incorporated into the species accounts. The appendix seems to have been an academic exercise without a lot of practical application. The Glossary covers most of the technical and specialized terms and is well organized. The Literature Cited is extensive, and although not a complete bibliography to Pennsylvania herpetology, it comes close.

Amphibians and Reptiles of Pennsylvania and the Northeast does

a very good job on Pennsylvania, but not the northeast. All measurements and ecological observations pertain to Pennsylvania specimens. It seems as if the other northeastern states were an afterthought, quickly tacked on the original manuscript. I recommend this book for anyone interested in or working on Pennsylvania reptiles and amphibians. For those interested in other northeastern states check out Klemens (1993) for Connecticut, Rhode Island, and southern Massachusetts; Hunter et al. (1999) for Maine and adjacent New Hampshire; and Breisch (in prep.) for New York.

THE ASSOCIATION OF REPTILIAN AND AMPHIBIAN VETERINARIANS

The Association of Reptilian and Amphibian Veterinarians (ARAV) ***is a nonprofit international organization of veterinarians and herpetologists founded in 1991. Our goal is to improve reptilian and amphibian veterinary care and husbandry through education, exchange of ideas and research.***

Membership is open to all interested parties, benefits include:

Quarterly Journal Peer reviewed, referenced, indexed and a concise information source for state-of-the-art herpetological veterinary medicine.

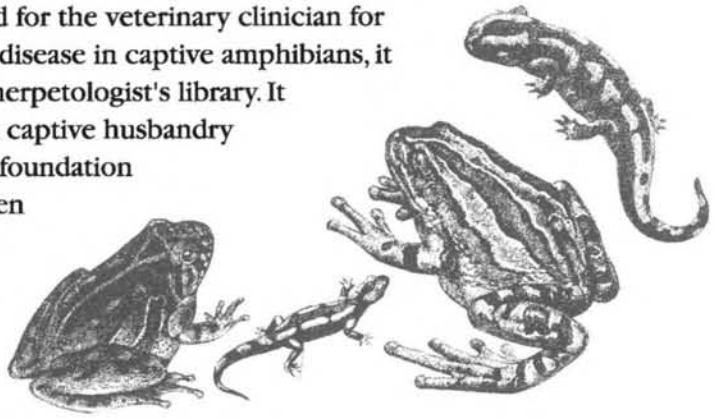
Annual Conference Members receive discount on tuition.

The Annual Conference and published Proceedings includes a wide variety of pertinent topics; nutrition, husbandry, infectious diseases, basic and advanced diagnostics, surgical and medical therapeutics, wetlabs and workshops designed to keep you current in an everchanging field.

The ARAV needs your participation. We invite you to join forces with more than 1,300 other professionals. Fill out the membership application and support the organization that is improving veterinary care of reptiles and amphibians.

For more information please contact: Charles J. Innis, VMD, VCA Westboro Animal Hospital 155 Turnpike Road Rt. 9, Westboro, MA 01581, 508-366-1444, Fax 508-366-6449, E-mail clemmys@aol.com, or visit our website at www.arav.org.

The Journal of Herpetological Medicine and Surgery includes these sections:



- **Techniques**
- **Roundtable**
- **Case Reports**
- **Nutrition Notes**
- **Announcements**
- **Pathology Pages**
- **Care-in-Captivity**
- **In My Experience**
- **What's Your Diagnosis**
- **Original Review Articles**
- **Literature and Book Reviews**

Amphibian Medicine and Captive Husbandry

edited by Kevin M. Wright, DVM and Brent R. Whitaker, MS, DVM

Original Edition 2001
570 pp. ISBN 0-89464-917-5 $140.00

Although this book was designed for the veterinary clinician for the diagnosis and treatment of disease in captive amphibians, it is also an essential part of any herpetologist's library. It covers the various aspects of amphibian captive husbandry and propagation while providing a firm foundation that enables the reader to evaluate a given husbandry routine. Fully illustrated, this volume contains 243 color pictures, 317 black and white images, and 54 tables that enhances the usefulness of the text.

CONTENTS IN BRIEF

Chapter 1. Evolution of the Amphibia
Chapter 2. Taxonomy of Amphibians Kept in Captivity
Chapter 3. Anatomy for the Clinician
Chapter 4. Applied Physiology
Chapter 5. Amphibian Husbandry and Housing
Chapter 6. Diets for Captive Amphibians
Chapter 7. Nutritional Disorders
Chapter 8. Clinical Techniques
Chapter 9. Restraint Techniques and Euthanasia
Chapter 10. Clinical Microbiology of Amphibians for the Exotic Practice
Chapter 11. Amphibian Hematology
Chapter 12. Water Quality
Chapter 13. Bacterial Diseases
Chapter 14. Mycoses
Chapter 15. Protozoa and Metazoa Infecting Amphibians
Chapter 16. Clinical Toxicology
Chapter 17. Trauma
Chapter 18. Idiopathic Syndromes
Chapter 19. The Amphibian Eye
Chapter 20. Diagnostic Imaging of Amphibians
Chapter 21. Surgical Techniques
Chapter 22. Reproduction
Chapter 23. Quarantine
Chapter 24. Pharmacotherapeutics
Chapter 25. Necropsy
Chapter 26. Spontaneous Neoplasia in Amphibia
Chapter 27. Pathology of Amphibia

Artwork and Slides Wanted for *HR*

We are always interested in obtaining illustrations of herpetological subjects for publication in *Herpetological Review*. Generally, original drawings should be of a scale that would permit reduction to fit a 90-mm wide column. Original art, or high quality photocopies, should be packaged to ensure safe delivery and sent to the Editor. Alternatively, we would be pleased to receive material in electronic format; consult the Editor for appropriate file formats and sizes.

Also, we are interested in evaluating outstanding color slides of amphibians and reptiles for possible use on future *HR* covers. When reviewing material for submission, photographers should keep in mind the vertical format of our covers. In addition to highlighting outstanding photography, our cover subjects should lend themselves to communication of biologically interesting information through accompanying text. If you would like to have your work considered, please contact the Editor ***prior*** to sending any slides. We prefer to review images as low-resolution JPEG files before requesting examination of original slides. Postal and e-mail addresses are listed on the inside front cover.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, and Current Research should be sent directly to the appropriate section editor. Send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, Herpetological History, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor or Managing Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Theodora Pinou; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Ecology & Evolutionary Biology, Yale University, P.O. Box 208106, New Haven, Connecticut 06520-8106, USA. Periodical postage rates are paid at New Haven, Connecticut with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Attn. Donald Schmitt, SSAR Membership Office, P.O. Box 253, Marceline, Missouri 64658, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Breck Bartholomew, SSAR Publications Secretary (address and contact numbers on inside front cover) regarding missing or damaged issues.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 740		US $440
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 740	$300

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2002 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Theodora Pinou, SSAR Treasurer, Department of Ecology & Evolutionary Biology, Osborn Memorial Labs, Yale University, 165 Prospect Street, New Haven, Connecticut 06520-8106, USA. Fax: (203) 432-5176; e-mail: theodora.pinou@yale.edu

Future Annual Meetings

2002 — Crown Center Hotel, Kansas City, Missouri, USA. 3–8 July (with ASIH, HL)
2003 — Hotel Tropical, Manaus, Brazil (with ASIH, HL)
2004 — University of Oklahoma, Norman, Oklahoma (with ASIH, HL)

Society for the Study of Amphibians and Reptiles
2002 Annual Meeting
together with
The Herpetologists' League
and
American Society of Ichthyologists and Herpetologists

3 – 8 July 2002
The Westin Crown Center Hotel
Kansas City, Missouri, USA

Keynote Address: "In and Across the Deep Blue Sea: Ages of Seaturtles and Dispersal of Oceania Lizards," by George Zug (Smithsonian Institution), The Herpetologists' League Distinguished Herpetologist for 2002.

SSAR Presidential Travelogues: "Between Rain Forest and Desert: Herpetofaunal Travels in West and Central Africa," by Prof. Dr. Wolfgang Böhme (Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany); "Travels in Kenya: Pondscape with Frog," Prof. Dr. David M. Green (Redpath Museum, McGill University, Montreal, Quebec, Canada).

Symposium: "Contemporary Herpetological Research: A Tribute to Robert Jaeger as 20-year Editor of *Herpetologica*." *Organizers:* Susan C. Walls, U.S. Geological Survey (susan_walls@usgs.gov) and Sharon E. Wise, Stephens College (swise@wc.stephens.edu).

Symposium: "Ecology and Evolution of Phytotelmic Anurans." *Organizer*: Richard Lehtinen, University of Michigan (rmlehtin@umich.edu).

Symposium: "Mixing Faunas: An Overview of Introduced Non-Indigenous Fishes, Amphibians, and Reptiles." *Organizer:* Walter Courtenay, Florida Atlantic University (courtenw@fau.edu).

Special Presentation to Commemorate The Herpetologists' League 50th Anniversary: "Phylogenetic Relationships, Behavioral Oddities, and Paedomorphic Tendencies Among the First Half Century of HL Herpetologists," by Whit Gibbons, Savannah River Ecology Laboratory (gibbons@srel.edu).

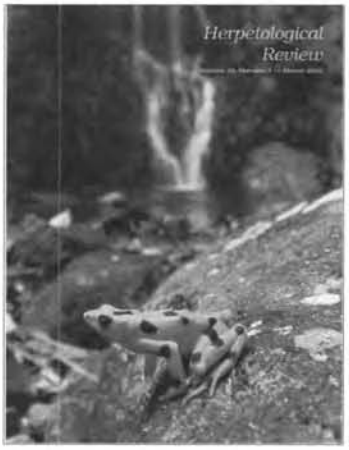
Contributed Paper and Poster Presentations: There will be several concurrent sessions each day throughout the conference.

SSAR Student Travel Awards: Awards of US $200 each are available. An applicant must be a student and a member of SSAR. Refer to page 210 of the December 2001 issue of *HR* for details.

Student Paper Awards: Henri Seibert prizes (US $200 each) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. Refer to the official Meeting Announcement for details and to *HR* 28(4):175 for recommendations to students entering the Seibert competition.

Social Activities: General Reception in the Century Ballroom, SSAR Herp Silent Auction, Graduate Student Reception, Saturday night Barbecue Dinner at historic Union Station Plaza, Graduate Student Reprint & Book Scavenge, SSAR/HL Auction, Joint Meeting Banquet.

HL Graduate Student Workshop: "Publishing in Scientific Journals: Process, Do's and Don'ts" (Tom Jenssen and Ken Dodd).



Multimedia Presentations: "Amphibians of the Appalachians," and "Herpetology of the West," by David Dennis and Eric Juterbock.

Costs: Preregistration US $285 regular, US $175 student, US $110 accompanying person. After May 3, 2002, costs are US $325, US $225 student. Online registration available at: <www.dce.ksu.edu/dce/cl/2002jointmeeting/>

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Further Details: The Meeting Announcement/Call for Papers was mailed to all members of SSAR, HL, and ASIH in January. It is also available as a PDF file at <www.dce.ksu.edu/dce/cl/2002jointmeeting/>. Anyone unable to download the PDF file may contact Henry Mushinsky, Department of Biology, University of South Florida, Tampa, Florida 33620-5150, USA; Tel. 813/974-5218, fax 813/974-3263; e-mail: Mushinsk@chuma1.cas.usf.edu.

About Our Cover: *Atelopus zeteki*

The endangered Panamanian Golden Frog (*Atelopus zeteki*) is restricted to streams along montane slopes of the Central Cordilleran cloud forests of western-central Panama (Lindquist & Hetherington 1998. Herpetologica 54:370–376). "Project Golden Frog" is the featured subject of a new section—"Zoo View"—making its debut in this issue of *HR* (see pages 10–12). Aside from its considerable conservation interest, *A. zeteki* plays an important cultural role in the lives of Panamanian people. Pre-Columbian indigenous people revered Golden Frogs and crafted gold and clay talismans in a variety of forms (frogs, people, jaguars) known to contemporary Panamanians as huacas/huacos. These ancient objects are sought by amateur archaeologists ("huaqueros"), and in turn are often sold to collectors for very high prices. Replicas are commonly found in jewelry stores in Panama. Local legend holds that chieftains of the Guaymí tribe would ascend the Pacific slope to the mountains of Gaital, Pajita, and Caracoral (in El Valle de Antón) annually as a sacred rite. This legend and others evolved into the myth that the Golden Frog would transform into gold huacas upon death. Hence, anyone seeing or possessing the frog alive would have good fortune visited upon them. Despite its status as a national symbol in modern Panama, few Panamanians have ever seen these frogs. Golden Frogs grace everything from t-shirts to lottery tickets. The above information is taken from the Project Golden Frog web site (http://ranadorada.org).

The genus *Atelopus* contains about 67 species, collectively known as "harlequin frogs." Although *A. zeteki* was originally described by Dunn (1933. Occas. Pap. Boston Soc. Nat. Hist. 8:65–79) as a subspecies of the highly variable *A. varius*, later study of skin toxins (Brown et al. 1977. Toxicon 15:115–128) and male vocalizations (Cocroft et al. 1990. Copeia 1990:631–643) supported recognition as a distinct species.

Lindquist and Hetherington (*op. cit.*) have provided evidence to support the hypothesis that coloration and behavior of juveniles is correlated with the absence of toxic skin compounds. Metamorphs and juveniles are cryptically colored, their dark green and dark brown to black dorsal markings closely matching their mossy boulder habitat. Adults are brightly marked—either uniformly yellow, or yellow with black bands or spots (as in the frog on our cover). This ontogenetic change in coloration—from cryptically-colored juveniles to gaudy, aposematic adults—is apparently accompanied by acquisition of highly toxic skin compounds, presumably the product of either dietary or symbiotic bacterial uptake (Daly et al. 1997. Toxicon 35:705–709). Further, non-toxic juveniles are secretive, while the conspicuously marked adults are diurnal, commonly observed in the open (Cocroft et al., *op. cit.*).

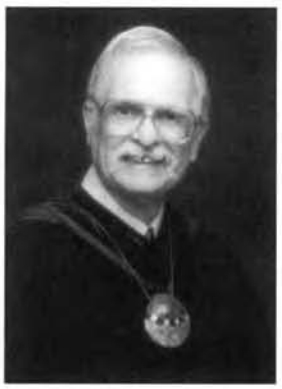
Our cover image was taken by **Guido Sterkendries**, one of Belgium's finest wildlife photographers. The adult frog was observed at one of the Project Golden Frog study sites east of El Valle de Anton, Panama. Sterkendries captured this image under natural light, using a Nikon F5 with a 17–35mm Nikor lens and Fuji Provia film (100 ASA). Because he wanted to show the frog in its native habitat, he used an aperture setting of f.8, which allowed the frog to be the main subject. Additional images of frogs and other subjects may be viewed at <www.sterkendries.com>. Separation and imaging of Sterkendries' photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

Secretary ..... John Matter (unopposed).
Treasurer ..... Theodora Pinou (unopposed).
Board of Directors (Class of 2004) .....
..... Joseph R. Mendelson and Gabriela Parra Olea.



HR Staff Changes

Recent changes to the editorial staff of *Herpetological Review* include the "retirements" of Joseph T. Collins (Section Editor, Geographic Distribution), Brian Hauge (Section Editor, Natural History Notes), Adam Summers (Associate Editor), Jennifer Pramuk (Copy Editor), Winston Card (Section Editor, Herpetological Husbandry), Jennifer Garrison (Section Editor, Current Research), and Travis Ryan (Section Editor, Legislation & Conservation). Collins' twelve-year tenure as Section Editor is especially noteworthy; in addition to this most recent tour of duty, Joe previously served as *HR* Editor and in various other capacities for SSAR. On behalf of the SSAR Board, the editors thank these folks for outstanding service to their colleagues and wish them well in future endeavors.

Joining the editorial team during 2001–2002 are Omar Torres-Carvajal (Current Research), Marc Hayes (Section Editor, Natural History Notes), Alan Richmond (Geographic Distribution), Robert Espinoza (Associate Editor), Ruston Hartdegen (Herpetological Husbandry), and Hugo Alamillo (Copy Editor).

NEWSNOTES

Carr Medal Awarded to Jay Savage

In late October 2001, the Florida Museum of Natural History presented the Archie F. Carr Medal to Jay M. Savage. The Carr Medal recognizes outstanding national and international contributions to the knowledge, understanding, and appreciation of our natural heritage. The award was named in honor of the late Archie Carr, University of Florida zoology professor and world authority on sea turtles. Recipients are chosen by a seven-member jury appointed by the director of the Museum. In conjunction with the award, Savage gave a public lecture, entitled "Le Sacre Du Printemps or Why Archie Always Liked Frogs."

As noted in the press release associated with this award, Savage is one of the world's leading herpetologists, field biologists, and

tropical conservationists. His 50-year career has added enormously to our knowledge of the classification and biogeography of amphibians and reptiles. His contributions are reflected in many ways, including a long list of important publications, and no fewer than 15 species of vertebrates named "*savagei*" in his honor by other biologists. A respected teacher and administrator, he has played a key role in building and supporting many of the most important organizations of present-day evolutionary biology, such as the Organization for Tropical Studies and the Society of Systematic Biologists. Past Carr Medal recipients include Edward O. Wilson, Thomas Eisner, Peter Raven, Jared Diamond, Thomas Lovejoy, and Michael Soulé.

SSAR and the herpetological community congratulate Jay Savage for this high honor.

e-mail: breck@herplit.com

The World Congress of Herpetology held its fourth meeting in December 2001 at the five-star Taj Exotica Hotel Resort at Bentota on the southwestern coast of Sri Lanka. Despite almost insurmountable national and international events that affected scheduling and disrupted travel plans (the Tamil Tiger terrorist attack on Sri Lanka's international airport last summer, the events of September 11 in the United States, and the dissolution of Sri Lanka's parliament and scheduling of national elections on December 5), the Congress convened on schedule in an idyllic tropical beach setting. Approximately 208 delegates from 34 countries (Table 1) attended six days of meetings, followed by a day of field trips to the nearby wetland preserves of Muthurajawela or Madhuganga.

First day cover of four endemic amphibian stamps issued (3 December 2001) to commemorate the Fourth World Congress of Herpetology. Featured are *Philautus femoralis, Rana gracilis, Theloderma schmarda,* and *Polypedates longinasus*.

After the Congress, delegates departed for cultural sites and national parks and preserves around the country. Attendees probably wished for more time to see Sri Lanka's biotic diversity and to enjoy the friendliness of its people.

THE HERPETOFAUNA OF SRI LANKA

An historical overview, current status with checklists

Anslem de Silva

2001

A new book covering the herpetofauna of Sri Lanka, authored by Conference Director Anslem de Silva, was issued to coincide with the meeting.

The purpose of the World Congress of Herpetology (WCH) is to bring together scientists and others, from all parts of the world, interested in the biology of amphibians and reptiles so that ideas and techniques may be exchanged and collaboration fostered. Previous Congresses were held in Canterbury (United Kingdom) in 1989, Adelaide (Australia) in 1993/4, and Prague (Czech Republic) in 1997. As highlights of the Congresses, internationally recognized scientists present plenary lectures featuring state-of-the-art knowledge, both as a retrospective of a distinguished career and as a stimulus for further thought and research. Past Congresses have emphasized plenary speakers and specially organized sessions, with contributed talks and posters given by other researchers as time and space permitted. At the Fourth World Congress, a similar protocol was followed but, due to last-minute changes in travel plans, several sessions and a number of talks had to be canceled. Most papers fell into the contributed category, but only after approval by the WCH Scientific Programme Committee. No more than two concurrent sessions were ongoing during any part of the Congress. Fortunately, the plenary lectures were excellent, and the reduced number of delegates allowed for much discussion and inter-personal interaction.

The Congress opened on the morning of 3 December with a procession featuring Sri Lankan dancers in traditional costumes playing drums, brass rams' horns, and finger cymbals. The procession was followed by the lighting of a ceremonial oil lamp by Congress organizers, visiting dignitaries (including Mrs. Shiranee Yasaratne, IUCN Country Representative for Sri Lanka), and representatives of the Executive Committee (EC). A special 4WCH first day cover and a set of postage stamps featuring four endemic Sri Lanka amphibians were issued, and a presentation was made of a special book on the herpetofauna of Sri Lanka from its author, Anslem de Silva, to Michael Tyler, Secretary General of the WCH. After brief introductions by members of the local committee and Michael Tyler, the Congress began with its first plenary lecture.

There were five plenary lectures: Anita Malhotra (Evolution of Asian vipers); Yehuda Werner (Foraging behavior in gekkonomorph lizards); Wolfgang Wüster (Pit vipers and South

Conference director Anslem de Silva chatting with Frankie Bossuyt.

American biogeography); David Warrell (Current trends in toxinology); Walter Hödl (Visual communication in anurans). Special sessions were held on the frog fauna of south Asia, habitat fragmentation and the conservation of herpetofauna, behavioral and morphological asymmetries, social aggregation in lizards, molecular ecology and evolution in lizards, and applied herpetology. Of special note is the launching of a new journal, *Applied Herpetology*, which will focus on applied or practical research involving amphibians and reptiles, such as methods to reduce the impacts of habitat fragmentation and mitigate threats to herpetofauna, veterinary or medical applications of herpetology, forensic herpetology, and new research and sampling techniques. Interested contributors or subscribers should contact Michael Lambert at the Natural Resources Unit of the University of Greenwich (m.r.k.Lambert@gre.ac.uk).

As might be expected from a Congress held in south Asia, many talks focused on the herpetofaunal diversity of southeast Asia, southern India (especially the eastern and western Ghats), and Sri Lanka. Many New World herpetologists are aware of Neotropical anuran diversity, especially within the genus *Eleutherodactylus*, but few may have been as aware of the high diversity of anurans in south India and Sri Lanka (see Dubois 1999). For example, 100 or more species within the family Rhacophoridae are estimated to be present on Sri Lanka alone, especially in the genus *Philautus* (or *Pseudophilautus*) (e.g., Bossuyt and Dubois 2001). Indeed, Sri Lanka may eventually be found to be inhabited by as many as 250 amphibian species (Das 2001). Other than a regional focus, no one discipline seemed more represented than others. Conservation themes were quite evident, although fortunately the amphibian faunas of south and southeast Asia do not appear to be undergoing the serious population declines that have affected amphibians in Australia, Central America, and elsewhere.

The business meeting of the Fourth World Congress was held on 5 December, but it was much more casual, even disorganized (disheveled?), than previous WCH business meetings. The financial arrangements in support of the Sri Lanka local committee (loans; travel by EC members) seem to have seriously challenged the WCH bank account, although organizers hope that the repayment of loans and proceeds from the Congress will eventually balance the books. Nominations for the International Herpetological and Executive committees were read but, because so few Executive Committee members were present, voting on the new candidates will take place at a later time. No venue or date was agreed upon for the Fifth World Congress of Herpetology, although Brazil, Singapore, and Japan were mentioned. The outgoing Secretary General, whose term ends in March 2002, stated that North Americans seemed not to have a serious interest in hosting a future Congress because of the number and size of existing herpetological meetings there; he would be delighted if a Central or South American organization made a formal proposal for the next Congress. The next WCH should take place in 2005 or sooner. There were no resolutions, and no new business was undertaken.

Social activities were more limited than at previous Congresses, due in part perhaps to the general curfew in effect during the elections. Even the sale of alcohol was banned during the elections, of perhaps modest concern to many herpetologists (known, as they are, for their consumption of grains and grapes during meeting socials). Evening films by Mark O'Shea and Rom Whitaker were shown, but most evenings were free for discussion, moonlit walks on the beach, or hunting frogs around a small pond on the hotel grounds. Day excursions were made by many delegates to Galapata Vihara, a 12th Century Buddhist temple, local sea turtle hatcheries, the spice gardens in a nearby village, and various diving and snorkeling locations. On 8 December, a buffet banquet was held on the lawn overlooking the Indian Ocean; a group of Sri Lankan traditional dancers entertained participants by performing acrobatic and story-telling dances accompanied by Sri Lankan music. A long auction followed.

TABLE 1. The number of delegates, by country, attending the Fourth World Congress of Herpetology, Bentota, Sri Lanka, 3–9 December 2001.

Austria	4
Australia	20
Belgium	1
Brazil	3
Canada	3
Czech Republic	2
Egypt	2
Finland	1
France	6
Germany	8
Hungary	4
India	13
Iran	2
Israel	7
Italy	2
Japan	16
Lebanon	2
Malawi	1
Malaysia	2
Netherlands	6
New Zealand	3
Poland	1
China (incl. Taiwan)	3
Russia	3
Singapore	2
South Africa	4
Spain	2
Sri Lanka	24
Sweden	7
Switzerland	1
U.A.E.	2
U.K.	29
U.S.A.	21
Venezuela	1

Six publications were issued just prior to or in conjunction with the Fourth World Congress, in addition to a hard cover 143 page book featuring 182 abstracts:

BAMBARADENIYA, C. N. B., AND V. N. SAMARASEKARA (EDS.). 2001. An Overview of the Threatened Herpetofauna of South Asia. IUCN Sri Lanka and Asia Regional Biodiversity Programme. Colombo, Sri Lanka. vi + 118 pp.

DE SILVA, A. 2001. The Herpetofauna of Sri Lanka. An historical overview, current status with checklists. Amphibia and Reptile Research Organization of Sri Lanka (ARROS). Peradeniya, Sri Lanka. 91 pp.

_____. (ED.). 2001. The Amphibia of Sri Lanka: Recent Research. Lyriocephalus (Special Issue) 4(1–2):1–173.

FERGUSON, W. 1877 (2001). Reptile Fauna of Ceylon. Facsimile Reprint. Society for the Study of Amphibians and Reptiles. Ithaca, New York. v + 42 pp.

RATHNAYAKE, N. D. 2001. An account of monitor lizards in Sri Lanka: status and distribution. Occasional Papers of the Amphibia and Reptile Research Organization of Sri Lanka. (1):1–10.

SOMAWEERA, R., K. UKUWELA, AND S. KARUNARATNE. 2001. Menikdena: a local herpetofauna hotspot. Occasional Papers of the Amphibia and Reptile Research Organization of Sri Lanka. (2):1–8.

In addition, three full color posters (Amphibians, Snakes, Reptiles) of Sri Lankan herpetofauna were available.

Despite incredible distractions which occurred at the most inopportune times, the local committee of the Fourth World Congress of Herpetology deserves high praise for organizing and carrying on with an enjoyable and instructive scientific program. I doubt most of us would have been able to rearrange the venue (from Colombo to Bentota) and program so completely, at a moment's notice, as did Anslem de Silva and his associates. One can only hope that the next World Congress will face fewer difficulties and be better attended. Herpetologists who did not come to Sri Lanka missed a memorable meeting, and a beautiful country and people.

Kansas Herpetological Society Annual Meeting

The KHS held its 28th Annual Meeting at Topeka Collegiate School in Topeka, Kansas, on 3–4 November 2001. Over 100 participants attended scientific paper sessions to listen to 28 talks on amphibians and reptiles by scientists and students from across the nation.

Megan Kearney, graduate student at Emporia State University, received the Howard K. Gloyd/Edward H. Taylor Scholarship, honoring the memory of two great biologists with strong ties to Kansas. The first Alan H. Kamb Grant for Research on Kansas Snakes to Curtis Schmidt, graduate student at Fort Hays State University, received the first Alan H. Kamb Grant for Research on Kansas Snakes. Daniel D. Fogell, University of Nebraska, Omaha, received the "The Suzanne L. & Joseph T. Collins Award for Excellence in Kansas Herpetology." "The Big Croaker Awards," sponsored by the Kansas Department of Wildlife and Parks, are given in recognition of diligent monitoring of amphibian populations in conjunction with the Kansas Amphibian Monitoring Program. This year's recipients were Mark and Kathy Sexson and Stanley D. Roth.

In 2002, the Society will meet in Lawrence, Kansas.

MEETINGS

Meetings Calendar

5–7 April 2002—Current Research on Herpetofauna of the Sonoran Desert II, Tucson, Arizona, USA. http://tucsonherpsociety.org.

18–20 April 2002—3rd International Symposium on *Emys orbicularis*, Kosice, Slovak Republic. Hosted by Vychodoslovenske Muzeum Kosice in association with Museum fur Tierkunde Dresden and DGHT Rheinbach. Information: Peter Havas, e-mail: havasp@vakke.slposta.sk or www.cassovia.sk/emys.

3–8 July 2002—45th Annual Meeting, Society for the Study of Amphibians and Reptiles, together with HL and ASIH. Crown Center Hotel, Kansas City, Missouri, USA. Refer to page 1 of this issue of *HR* for details.

18–21 July 2002—26th Annual Meeting of the International Herpetological Symposium, Sheraton Westport Hotel Plaza, St. Louis, Missouri, USA. Information: www.kingsnake.com/ihs/26meeting.html.

SSAR Seeks New Webmaster

After serving the Society since 1993 in this capacity, George Pisani has decided to pursue other interests more like his research and recreation! Specific qualities of the webmaster we hope to find to replace him are:

- experience and demonstrated capability in designing sites which emphasize high-quality content; and, ease of delivery of that content to a broad constituency worldwide, who frequently lack the latest hardware, software and net-backbone structure.
- demonstrated ability in tasteful design, which is as important as coding ability.
- able to complete site update work on a continual timely basis, while home or travelling.
- ability to work as part of a group, and to provide good IT counsel to the Board.
- familiarity with structuring and maintaining searchable online databases.
- familiarity with establishing and maintaining secure-transaction "shopping cart" web interfaces.

Some examples of the things the Society hopes to accomplish are: searchable database of *Herp Review* natural history notes archives, searchable database of *Herp Review* geographic distribution, society directory, online subscription service, online book orders, online dues renewal, tables of contents of our publications, and more.

There is funding to assist in the accomplishment of certain of these things, which may be used by the webmaster to secure outside help if needed.

Interested parties should e-mail [in RTF format, please] a CV and letter of interest to both: Breck Bartholomew <breck@herplit.com> and to George Pisani <gpisani@falcon.cc.ku.edu>. Be certain to include URLs of your current sites.

OBITUARIES

Herpetological Review, 2002, 33(1), 6–7.

Edwin H. Colbert
1905–2001

MARK A. NORELL
Division of Paleontology, American Museum of Natural History
Central Park West at 79th Street, New York, New York 10024-5192, USA
e-mail: norell@amnh.org

Dr. Edwin "Ned" Colbert passed away during the night of 15 November 2001 at the age of 96. Although not ill, his frailty and age made his death not unexpected. Ned Colbert had a lifelong fascination with dinosaurs and prehistoric life in a career that spanned over 75 years. He was active right up to the end, recently informing members of the staff of the Museum of Northern Arizona (where he has worked since his retirement at the AMNH) with what he hoped to accomplish over the next ten years. A report in an Arizona paper has him sitting up in bed and delivering his last lecture on paleontology minutes before his death.

I first met Ned when I was an undergraduate in the late 1970's on my way home from a fossil collecting trip to Colorado. While travelling through Flagstaff we stopped in at the Museum of Northern Arizona. Ned greeted us with enthusiasm, showed us his collections from Antarctica, *Coelophysis* from Ghost Ranch and the recently discovered *Scutellosaurus*. He was generous with his reprints—most of which I still have. It wasn't until years later, after I assumed his old position of dinosaur curator at the American Museum of Natural History that our paths crossed again.

One of my first activities at the museum was involvement in the dismantling and reorganization of the dinosaur halls. Colbert had overseen the renovation of the existing galleries. Colbert organized the old halls along temporal lines with a Hall of Jurassic or early dinosaurs followed by a Hall of Late Dinosaurs. The old halls were dimly lit with lumbering sauropods and a Godzilla-like Tyrannosaurus. Colbert's wife Margaret (daughter of William Diller Matthew) had drawn the chalk murals on the walls of the Early Dinosaur Hall. The old halls were Ned's—and they were New York icons.

The renovation of the 90's was a source of discord between the contemporary AMNH curatorial staff and Ned. The old halls were completely demolished, and replaced by brightly lit ones. The new halls were arranged cladistically—a methodology which Colbert never ascribed to. Yet, it is notable that shortly before his death, and in one of his last publications (a paper on drepanosaurs based on specimens from New Jersey) a cladogram appears.

After this rocky beginning our common interest in fossil specimens, fieldwork, questions about the past, and our fondness for the American Museum allowed our relationship to progress. I spoke to him about some of his reminiscences of the fabled AMNH fossil hunter Barnum Brown, about the direction of the department of which he had served as chair, and of several other matters only shortly before his passing.

During his career Colbert's published over 400 scientific papers on a broad range of themes. Although Colbert is thought of mostly as a dinosaur paleontologist (specializing in the early history of these reptiles), some of his greatest achievements were in other areas. In 1969, soon before retirement, Colbert led a NSF-sponsored team to Antarctica in search of fossil remains. There he collected remains of several Triassic animals including the reptile-like mammal *Lystosaurus*. As *Lystrosaurus* specimens were also known from South Africa and South America, this discovery provided powerful corroboration for the emergent theory of continental drift. This work was highlighted in his 1973 book "Wandering Lands and Animals."

Colbert was something of an innovator in the field of paleobiology as well. In the 1960's he became interested in empirically addressing the question of the weights of dinosaurs. Cleverly he constructed models of these animals and measured their displacement volume, scaled them up and multiplied them by a density calculated from living animals to arrive at a value for mass. He also examined the question of heterothermy in large animals by doing experiments on captive alligators.

Colbert will be most remembered to those outside the microcosm of dinosaur science as a great popularizer of paleontology. He wrote several books on the topic, keeping busy well into his 80's. Colbert's first book was "The Dinosaur Book: the Ruling Reptiles and their Relatives" in 1945. This was followed by several more on dinosaurs and fossil reptiles (notably "The Age of Reptiles" in 1965), on the history of paleontology and dinosaur collections (the biography of William Diller Matthew in 1992 and "The Great Dinosaur Hunters" in 1968) and the autobiographical "A Fossil Hunter's Notebook" (1980) and "Digging into the Past" (1989). Colbert also wrote the widely used textbook "Evolution of the Vertebrates" in 1991. Many of Colbert's writings are still in print.

Colbert started at the American Museum in 1929, shortly after receiving his Ph.D. at Columbia University in 1928 under the supervision of William King Gregory. The American Museum of that era was an exciting place—with paleontologists like Granger, Simpson, Matthew, and Brown recovering specimens from across the globe. Roy Chapman Andrews was finishing in Central Asia and coming back to take on an administrative role in the museum. Ned Colbert was one of the last tangible links to that era. His tenure at the museum started as a protegé of Henry Fairfield Osborn, founder of the Department of Vertebrate Paleontology. Osborn was an iconic (but in Colbert's own words "difficult") figure who new Marsh, Cope, worked with Huxley and met Darwin. Colbert's early work was almost totally restricted to fossil mammals, and he assisted Osborn ("did the donkey work") on Osborn's well-known "Proboscidea" monograph and other projects.

It was not until the 1940's that Colbert began his work in the Mesozoic. Some of his early trips were to East Texas accompany-

ing Al Romer. His most notable dinosaur was the excavation of the Ghost Ranch *Coelophysis* quarries in the 1950's. At these quarries Colbert's team excavated a tremendous sample of the primitive theropod dinosaur *Coelophysis*. This work was documented in the popular book "The Little Dinosaurs of Ghost Ranch" in 1995.

Dr. Colbert was a member of the National Academy of Sciences. His students are many and include John Ostrom of Yale, Eugene Gaffney of the American Museum of Natural History, and Dale Russell. He is survived by his wife Margaret and several grand- and great-grandchildren.

Ned Colbert

RICHARD G. ZWEIFEL
P.O. Box 16354
Portal, Arizona 85632, USA

Ned Colbert's career spanned 40 productive years at the American Museum of Natural History and following his retirement, another 20 years in association with the Museum of Northern Arizona, Flagstaff. Although best known for his work with fossil reptiles, Ned's administrative and research paths crossed those of Recent herpetology.

In 1943, Albert Parr, newly appointed Director of the Museum, abolished the existing departmental arrangement and instituted a vertical organization in which curators dealing with fossil and Recent organisms of a given sort were to be integrated into a single department. The curatorial staff expressed considerable disagreement with this new order but to no avail. Thus, Ned became Chairman of the Department of Amphibians and Reptiles with Charles M. Bogert the only other Curator in residence (James Oliver was in the Navy). Fortunately, Colbert and Bogert got along well and the departmental reorganization was rescinded not long after its implementation.

Ned got in his herpetological field time with a genus that transcended the fossil boundary, *Alligator*, when he joined Bogert and Raymond B. Cowles in a study of the beast's temperature tolerances (Colbert et al. 1946; see also Myers and Zweifel 1993, fig. 3). In another contribution (Colbert 1967), Ned studied the morphology of *Draco* in order to illuminate the analogous gliding mechanism of a Triassic reptile (Colbert 1966).

Ned's was a life well spent, and I am proud to have been within his broad circle of friends and colleagues.

Marvin Max Hensley (1922–2000)

DEAN PREMO
White Water Associates, Inc., 429 River Lane, P.O. Box 27
Amasa, Michigan 49903, USA
e-mail: dbpremo@up.net

Some biologists never get the knack of catching a snake. The slightest hesitation results in a missed opportunity. Even in his later years, however, Max Hensley would drop to both knees with surprising quickness and come up with his scaly target gently cradled for companions to appreciate and photograph. It is a curious irony that today's scientific community values biodiversity more and more, yet produces fewer and fewer biologists with the ability to identify organisms and understand their ecology. Dr. Marvin M. Hensley (Max) was such a biologist and he shared his knowledge and enthusiasm with many students and friends.

Max Hensley was born 4 April 1922 in Keyesport, Illinois. After a rural growing-up, he received his AB degree at Greenville College in the natural sciences in 1946. He went on for a MS at University of Illinois (1948), and a Ph.D. at Cornell (1951). Max's zoological education was interrupted by a stint in the Navy, serving from 1943 to 1946. Max achieved the rank of Lieutenant Junior Grade and he was quietly proud of his service during World War II.

Dr. Hensley began his teaching career as an Assistant Professor of Biology at Gettysburg College in 1951. He had been an Associate Professor for about a year at Gettysburg when Michigan State University hired him as an Assistant Professor in Zoology in 1956. At MSU, he was an Associate Professor from 1959 through 1961 and Professor from 1962 until his retirement in 1986. During the early years of his career, he interacted a great deal with Sherman Minton of Indiana University and Phillip Smith of the Illinois Natural History Survey. Once, the three men made a collecting trip to Mexico. In fact, Max made several collecting trips to this part of the world and, in later years, traveled to Africa and the Galapagos Islands. His 35mm slides and stories of those travels greatly benefitted his students in zoology and biogeography.

Dr. Hensley authored or coauthored 24 scientific papers, but always viewed teaching as his most important job. He was loved by his herp undergraduate and graduate students and was not only a good teacher to them, but advisor and friend. His honest advice and careful criticism were valued. His lectures were full of information and his examinations were challenging. Max felt it was important to know historical figures in science and often his exams required descriptions of scientific contributions of several

people. Humor was there too, and sometimes in unexpected places (Max stumped me by one name in a list of "scientists" during my written comprehensive exams—Adolph Coors). As a tribute to his dedication to teaching, the College of Natural Science Alumni Association awarded Dr. Hensley the Distinguished Faculty Award in 1985.

Max was a longtime member of the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, Society for the Study of Amphibians and Reptiles, American Ornithological Union, and American Society of Mammalogists. At herp meetings, Max was especially gregarious and a favorite person with whom to visit. At scientific meetings and in the classroom, Max was careful not to intimidate students with his knowledge and was always encouraging and friendly.

Max was an excellent field herpetologist. His colleague for many years at Michigan State University, J. Alan Holman, remembers trips to Michigan's Upper Peninsula with Max. Max would ferret out good collecting places in this northern land and quickly find ring-necked snakes, red-bellied snakes, eastern fox snakes, four-toed salamanders, and more. Dr. Hensley's herp class field trips were legendary for their organization and success. All captured animals were photographed and carefully returned to the proper habitat. Max had no use for herpetologists that over-collected and was always very good to the environment where he was collecting. He replaced every log and bunch of leaves to the proper place and taught his students to do the same. When Max kept live herps, they were exceedingly well cared for and lived long healthy lives. Perhaps his most famous pet was a Mexican beaded lizard (*Heloderma horridum*) that impressed thousands of students over the years and lived exclusively on a diet of raw eggs that it rather indelicately licked from a bowl.

Max loved music of all kinds, but none more than an old- time music jam session (with guitars, fiddles, mandolins, and so on). Whenever such impromptu concerts happened at his house, he would produce a homemade contraption composed of a washboard, cowbell, squeeze horn, wood blocks, and other soundmakers. Max played this "swamp fiddle" with all the flair and moves of a great bassist.

Dr. Hensley was generous of more than his time. In 1995 he established the "Dr. Marvin Hensley Endowed Scholarship in Zoology." In 1995 he also established, "The Dr. Marvin Hensley Endowed Fellowships in Science" with selections made by the College of Natural Science at MSU. Max also created the "Dr. Marvin Hensley Endowment for Vertebrate Collections in the Museum," a generous fund dedicated to the care of the vertebrate collections at MSU Museum. Over the years, Max contributed many valuable herp specimens to the Museum, not only from Michigan but from Mexico, Appalachia, and Arizona. Max was also a dedicated fan of college wrestling and created an endowment to the Ralph Young Fund at MSU for that purpose.

Max Hensley died 19 February 2000 from a heart attack and complications associated with diabetes. He was living in Sarasota, Florida. He is sorely missed by his friends and fellow zoologists, but his memory always invokes smiles and pleasant thoughts of time spent with this humble and generous person.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **Eli Greenbaum** or **Omar Torres-Carvajal**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can now be found at: http://www.herplit.com/contents.

Systematics and Histocompatability of a Parthenogenetic Teiid

Cnemidophorus laredoensis is a diploid parthenogenetic lizard that arose from a hybrid between the gonochoristic species *C. gularis* and *C. sexlineatus*. The authors used skin grafting to measure the extent of homogeneity in *C. laredoensis*, and to assess whether this taxon represents a single species or a complex of species derived from two or more parthenogenetic hybrids. The authors collected 20 live lizards from six sites in Texas, maintained them in a laboratory, transplanted skin grafts between selected taxa, and monitored the animals until they died. Thirteen of the 20 individuals were tested for ploidy level. Individuals of *C. laredoensis* rejected grafts from *C. gularis* and *C. sexlineatus* after18–95 days; both of the latter species rejected grafts from *C. laredoensis*. Several hybrid individuals were tested as well, with differing results. Reciprocal grafts among 17 individuals of *C. laredoensis* from several localities were accepted; three individuals rejected some or all of their grafts. The results suggest that *C. laredoensis* is derived from a single hybrid ancestor (*C. gularis* x *C. sexlineatus*), and postformational mutations may explain the unidirectional rejections. The authors contend that the name *C. laredoensis* should be restricted to populations in Texas and Mexico that are "diagnostically distinct" with the parthenogenetic species described in 1973.

ABUHTEBA, R. M., J. M. WALKER, AND J. E. CORDES. 2000. Genetic homogeneity based on skin histocompatibility and the evolution and systematics of parthenogenetic *Cnemidophorus laredoensis* (Sauria: Teiidae). Canadian Journal of Zoology 78:895–904.

The Smallest Amniote is a Gecko

The West Indies are considered to be a "hotspot" of biodiversity because of the large number of endemic species and rapid rate of deforestation. The authors describe a new gecko of the genus *Sphaerodactylus* from the province of Pedernales in the Dominican Republic. The new species (*S. ariasae*) is most closely related to *S. streptophorus*. The gecko was collected in leaf litter of xeric woods over limestone substratum. The new species and *S. parthenopion* are tied for the distinction of world's smallest

amniote—the dwarf chameleon *Brookesia tuberculata* is a close second. The small body size of these species creates problems with water loss. These animals have circumvented the physiological constraint by living in humid microhabitats.

HEDGES, S. B., AND R. THOMAS. 2001. At the lower size limit in amniote vertebrates: a new diminutive lizard from the West Indies. Caribbean Journal of Science 37:168–173.

An Internet Database of Crotaline Venoms

Many snake venoms contain disintegrins, metalloproteinases, and fibrinolytic enzymes—these proteins may have important applications to the treatment of cancer, cardiovascular problems, and cerebromuscular disorders. North American crotaline venom studies have been limited to a handful of taxa because some species are rare or endangered, and difficult to obtain. The authors created a database with information about snakes in their serpentarium, including: (1) locality, weight, length, and sex; (2) feeding; (3) history of weight and length; (4) venom storage; (5) biochemical properties of venom samples, including electrophoretic filtration, anion and cation exchange chromatography, hemorrhagic assay, antihemorrhagic assay, fibrinolytic activity, antifibrinolytic activity, hide powder azure assay, gelatinase assay, and monoclonal antibody production. Detailed instructions are given for database queries, and biochemical venom properties are given for eighteen taxa. The Natural Toxins Research Center Database (http://ntri.tamuk.edu/snake_database/snake.lookup.html) has information about 250 snakes, which represent 11 species and 20 subspecies.

Edge Effects on Costa Rican Anoles and Frogs

Habitat destruction and fragmentation are two of the leading causes of herpetofaunal declines worldwide. The authors' objectives were to see how edge effects: (1) change the abundance of *Eleutherodactylus* frogs and *Norops* lizards; (2) affect parasite infestations of *Norops*; and (3) change the temporal (daily and seasonal) distribution of all encountered amphibians and reptiles. The authors placed 44 pairs of 10 x 10 m plots in small, medium, and large forest fragments; plots were located close to forest edges or in the center of forest fragments. Data on numerous habitat variables were collected from each plot. Overall, 784 individuals of reptiles and amphibians (18 species) were collected during the study. Two species of *Norops* were abundant in edge plots during the dry season, but switched their preference to interior plots during the wet season. More ectoparasites were present on lizards examined from interior plots. Two species of *Eleutherodactylus* (*E. podiciferus and E. cruentus*) were significantly less abundant in edge plots than in interior plots. Three other species of this genus (*E. ridens, E. stejnegerianus,* and *E. vocator*) were more evenly distributed, but became more abundant in interior plots during the rainy season. There are numerous hypotheses to explain the observed seasonal shifts.

Antipredator Behavior of an Australian Gecko

Previous studies have documented variation in the way populations of a given species cope with differences in predation. In many cases, local adaptation to predation pressure is possible, but can be constrained by gene flow among populations. The authors examined antisnake responses of populations of velvet geckos (*Oedura lesueurii*) to the broad-headed snake (*Hoplocephalus bungaroides*), a species that feeds primarily on geckos. The phylogenetic relationships of 15 populations of velvet geckos from coastal New South Wales, Australia were examined with 35 allozymes to identify genetic groups. Wild-caught (predator experienced) and captive-born (predator naive) geckos were tested for their reactions to unscented rocks, rocks scented with cologne, and rocks scented with integumentary chemicals from broad-headed snakes. Behavioral data was analyzed with ANOVA and log-linear models. Geckos exhibited a higher rate of tongue flicking and spent significantly more time crawling and stationary while pressed against the surface of snake-scented rocks if they were from populations that were sympatric with populations of broad-headed snakes. Other antipredatory behaviors did not vary across populations of geckos. Phylogenetically independent contrasts suggested snake distribution might have driven the evolution of antisnake behavior in velvet geckos. These results suggest local adaptation to predation pressure, which is not constrained by gene flow in the studied populations of velvet geckos.

Trophobiosis Between Geckos and Insects in Madagascar

Behaviors performed by ants can serve as a stimulus for certain insects to secrete honeydew—this type of interaction is known as trophobiosis. The authors observed trophobiosis between planthoppers of the family Flatidae and three species of *Phelsuma* (*P. madagascariensis kochi, P. mutabilis, P. abbotti*), three unidentified species of *Lygodactylus,* and *Homopholis sakalava.* Geckos rhythmically bounced their heads on the back of a tree to produce vibrations; this stimulus caused cicadas to secrete honeydew from their abdomens, which was licked off by the geckos. It is likely that the geckos are exploiting a preexisting

trophobiosis interaction between ants and the cicadas.

Dewlap and Dorsal Color Variation in an Anole

Studies on guppies have demonstrated that differences in spectral sensitivity can undergo selection for color patterns that minimize predator detection while remaining conspicuous to conspecifics. The dewlap of *Anolis conspersus* reflects light near ultraviolet wavelengths, but its ancestor (*A. grahami*) has a long wavelength-reflective dewlap. The author studied variation in dorsal coloration of adult male *A. conspersus* and its relationship to light conditions and background color. He also compared how dorsal and dewlap coloration affects crypsis, and how the colors may have evolved. The author collected data about dorsal and dewlap radiance with a spectrophotometer, and ambient habitat light with a hemispherical cosine receptor. Data were analyzed with PCA, DFA, ANOVA tests, and the color segment method. Three color morphs were identified (brown, green, blue), and each had relatively consistent patterns of dorsal and dewlap reflectance. However, the blue morph was found to overlap with the other two morphs in several characteristics. The evolution of the dewlap color may be a result of selection against evaporative water loss and not salience within low-light habitats. Although many body regions were inconspicuous against natural backgrounds, some areas (e.g., brightly colored heads) contrasted with background tree bark and leaves.

Causes of Frog Declines in California

Declines of *Rana aurora* populations of western North America have been attributed to global warming, UV radiation, airborne contaminants, disease, and introduced species. The authors examined hypotheses of climate change, UV radiation, pesticides, and habitat destruction because each has specific predictions for spatial patterns of declines. Historical records of distribution were collected from museums, literature records, field surveys, and correspondence with local naturalists. Localities were mapped onto ArcView version 3.0 GIS software, and mean annual precipitation was derived from a Teale Data Center digital precipitation map of California. Data also were collected about wind direction, proximity to agricultural areas, and agricultural land use. Statistical analyses were performed with Mann-Whitney rank tests, χ^2, Pearson product-moment correlations, and multiple logistic regressions. A number of additional analyses were made to test the robustness of the results to possible data errors. Results indicated that frog populations show a clear elevational gradient, with fewer frogs at higher elevations—this observation is consistent with UV radiation as a causal factor for declines, but further research is needed. Wind-borne agrochemicals may be an important factor in frog declines as well. Efforts to test whether disease or introduced species are affecting frog populations are exacerbated by the dearth of available information.

ZOO VIEW

Editor's Note: With this issue, we introduce a new feature to our readers—"Zoo View." The Section Editor is James B. Murphy. From 1966 to his retirement thirty years later, Murphy was in charge of the Department of Herpetology at the Dallas Zoo. Currently, he is a Smithsonian Research Associate in the Department of Herpetology at the National Zoological Park in Washington, DC. He has published three books on captive management of herpetofauna and a number of papers, book chapters, and bulletins on topics such as the natural history of Mexican rattlesnakes, ethological and reproductive studies on a variety of amphibians and reptiles, zoo history and philosophy, and husbandry. Murphy's long involvement in the zoo world and with academic research make him uniquely qualified to oversee this new column. Below, he provides an introduction.—RWH.

During the past few years, I have been working on a book, which will be published by SSAR, focusing on the history of zoo herpetology. As I searched the literature, it became clear that zoo and aquarium workers were involved in a number of interesting and important projects. It was also apparent that many of these initiatives were not well known to other herpetologists outside the zoo community. To remedy this situation, this column featuring zoo and aquarium programs and issues relevant to zoo personnel will be a regular section in *Herpetological Review*.

My plan is to invite colleagues worldwide to highlight those areas which are important to them and share their experiences and insights with our entire community. I foresee future columns addressing conservation, education, captive and medical management, history, philosophy, book reviews, announcements of upcoming events, and biographical sketches of important zoo and aquarium workers. Some columns may include tours of amphibian and reptile facilities. Periodically, academic colleagues will be asked to provide guidance to improve zoo programs, such as beginning a research investigation which will lead to publishable results and that can be accomplished in a zoo setting. My hope is that publicizing these elements broadly will lead to improved communication among all subsets within our discipline, resulting in meaningful collaborations.

Before attending the HL/SSAR meeting last year, I traveled to the Detroit Zoological Institute to see the recently opened National Amphibian Conservation Center. This edifice is superb and I encourage all herpetologists to visit—an entire building has been dedicated to amphibians and their biology for the first time. Excited zoo goers pack the public area. Clearly, amphibians are exceedingly popular and the zoo administrators at the Institute, especially Director Ron Kagan, deserve credit for taking a risk to show something other than a charismatic mega-vertebrate. Curator Dr. Kevin Zippel is justifiably proud of the many accomplishments already achieved and, as he explained the work with the Panamanian golden frog, I am convinced that this undertaking is a worthy introduction for this column.

I invite all colleagues to submit materials to me for future columns. My e-mail and postal addresses are listed on the inside cover of this issue.

—James B. Murphy, Section Editor

Conserving the Panamanian Golden Frog: Proyecto Rana Dorada

KEVIN ZIPPEL
National Amphibian Conservation Center , Detroit Zoological Institute
8450 West Ten Mile Road, Royal Oak, Michigan 48068-0039, USA
e-mail: ZippelK@zoo.ci.detroit.mi.us

Proyecto Rana Dorada (a.k.a., Project Golden Frog) is a proactive conservation initiative with the primary goal of preventing the extinction of one of the world's most recognizable, culturally significant, and endangered amphibians, the Panamanian golden frog (*Atelopus zeteki*). Wild populations are currently threatened with habitat loss and fragmentation, illegal collection for national and international pet trades, and a fungal epizootic (chytridiomycosis) that is extirpating mid- and high-elevation amphibian populations in Central America and throughout the world. Extrapolation of current trends suggests this species might be extinct within the next five years; all *Atelopus* in neighboring Costa Rica are apparently already gone from these same threats.

Our conservation efforts fall into three main areas: field studies, captive propagation, and education.

1. We have established three study sites within the protected boundaries of a national park to investigate various aspects of the species' biology, such as habitat requirements, seasonal activity patterns, territoriality, reproductive behavior, and dispersal. A four-wheel-drive vehicle was recently purchased to allow our Panamanian field researchers to collect data at each of these sites weekly. In addition, data loggers continuously monitor humidity and air and water temperatures. This information helps us understand how the frogs use their environment and provides vital data for the captive husbandry program. Our field team has collected invaluable photo-and video-documentation of golden frog behaviors, habitats, human impacts, and project progress. From our personal observations and personal communications with Karen Lips, we believe that chytridiomycosis has not yet arrived in golden frog habitat, but that it is currently threatening the last stronghold of the next western congener (*Atelopus varius*) with extinction. Ideally, a conservation program for this species should be initiated as well, as it is in imminent danger of disappearing from Panama and from the planet.

In addition to the threat of encroaching disease, the golden frog is also being threatened by overcollection for illegal national and international pet trades, and by habitat degradation/fragmentation in what little habitat remains.

2. As a precautionary measure against extinction of golden frogs, small assurance populations are being maintained and bred in captivity. We have already produced hundreds of offspring, which are being distributed to AZA-accredited zoos participating in the breeding program. Our intent is to utilize captive-bred specimens for reintroduction programs, in the event that (and only if) wild populations become extinct. To alleviate pressure on wild populations, we would also like to develop a breeding program in Panama where we can extend our captive expertise to Panamanian biologists. Together we will work toward the establishment of a breeding and educational facility, potentially at the El Nispero Zoo in El Valle.

3. Project educators are working to disseminate information from the field studies and captive program to raise awareness among

The golden frog inhabits cool, clear, cascading streams or 'quebradas' in low- to mid-elevation primary rainforest.

Project members scout potential golden frog habitat from atop a cleared hilltop.

Project members prepare to 'dust' a frog in fluorescent powder for tracking studies.

the Panamanian public regarding the plight of this culturally important animal. Informative fliers describing the golden frog's natural history and conservation status are being designed for distribution to Panamanian zoos and schools, and a bilingual Project website <www.ranadorada.org> disseminates information and progress internationally. A fundamental aim of this project is to provide opportunities for Panamanian and U.S. students to be trained and actively involved in population monitoring and public education. Students work closely with professional biologists within Panama's national parks to establish a continuous amphibian population-monitoring program. We are also raising funds to host a workshop for school teachers in Panama to provide them with detailed curricula to teach their students about the cultural history and conservation plight of their golden frog.

PGF recently received a US $25,100 grant from Disney's Animal Kingdom. Thanks to their generosity, we will be able to support another year of continued field studies and initiate our in-country education program. PGF would like to thank Disney and the other institutions and individuals that have generously given funds and/or institutional support to the Project: American Zoo and Aquarium Association, Autoridad Nacional del Ambiente de Panamá, Baltimore Zoo, Bay Foundation, Cincinnati Zoo, Círculo Herpetológico de Panamá, Cleveland Metroparks Zoo, Columbus Zoo, Detroit Zoo, Indiana University, Jennifer Nolan, John Ball Zoo, Lee University, Miami Metrozoo, Oklahoma City Zoo, Potawatomi Zoo, Riverbanks Zoo, Roger Williams Park Zoo, Smithsonian Tropical Research Institute, St. Louis Zoo, Wildlife Conservation Society, and the Woodland Park Zoo. For further information on PGF, please contact Project Coordinator Kevin Zippel (e-mail: kzippel@detroitzoo.org). Wildlife photographer Guido Sterkendries, whose photographs accompany this article, has been documenting the project. Check out his website at <www.sterkendries.com> for some spectacular images of herps.

In addition to coordinating this important effort for the golden frog, the Detroit Zoological Institute financially supports publication of *Froglog*, newsletter of the Declining Amphibian Populations Task Force. I am proud to say that zoo and aquarium workers have been the major contributors sustaining Task Force operations since the beginning.

"Intraspecific Variation of the Hemipenis," A Correction, with Comments on Other Erroneous Descriptions

HERNDON G. DOWLING
Rendalia Biologists, 1811 Rendalia Motorway
Talladega, Alabama 35160-4573, USA
e-mail: hdowling@coosavalley.net

The morphology of the snake hemipenis has been found to be an excellent indicator of snake relationships at many taxonomic levels. Utilized mainly at the level of genera and higher categories (e.g., Bogert 1940; Cope 1895; Dunn 1928), it has also proven to be a valuable guide at the level of species and subspecies. It was with this background that I stated (Dowling 1967) that hemipenes "may give better information on the genetic relationships [of snakes] than some habit- or habitat-correlated characteristics." Recent molecular studies have tended to confirm this statement (e.g., Vidal et al. 2000).

Thus, I was surprised to find that Zaher and Prudente (1999), after quoting the above observation, stated that "Such a belief is here viewed with caution." They stated that interspecific variation is common, and that intraspecific variation is well known. These, of course, are not new findings. As noted above, minor interspecific hemipenial variation is often used as one of the characters for the recognition of the individual species in a genus (e.g., Duellman 1958). Also, although intraspecific variation is usually found in minor characters (size of spines, numbers of calyces; e.g., Keiser 1969) and has not often been studied in detail, it has been recognized for many years and it occasionally has been used as a taxonomic feature for the recognition of subspecies (e.g., the description of *Coluber constrictor priapus* Dunn and Wood 1939). [The degree of intraspecific variation reported for the hemipenis (and female cloaca) in *Calamaria lumbricoidea* (Inger and Marx 1962) has not been found in any other taxon, and may be unique.] I wondered, therefore, what had led Zaher and Prudente to question the inherent stability of hemipenial characters.

The basis of their comment was to be found in their descriptions of hemipenial variation in two genera of Neotropical xenodontid snakes, *Siphlophis* and *Tripanurgos*, and I here offer an explanation for their observations of major "interspecific and intraspecific variations" in these two genera.

From their examination of 27 specimens, Zaher and Prudente (1999) described two apparent morphological states in the everted hemipenes of five species of *Siphlophis* and in the monotypic genus *Tripanurgos*. They labeled these the "Y-shaped condition" and the "T-shaped condition." If, indeed, hemipenes of individual species varied so widely as their illustrations suggest, hemipenes would lose much of their value as taxonomic characters. Fortunately, this is not the case.

Although "[They] reject the possibility that these different types are due to a preservation artifact ...," in fact, this is what the "T-

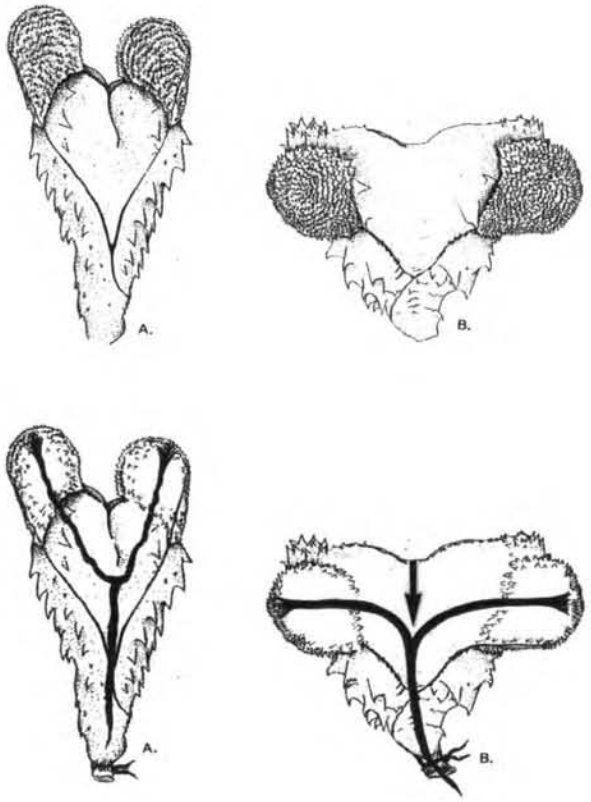

FIG. 1. "Y-shaped" (A) and "T-shaped" (B) hemipenes of *"Tripanurgos" [= Siphlophis] compressus*. UPPER: as presented in Fig. 2 of Zaher and Prudente (1999). LOWER: Redrawn from this figure (with basal ends added to show the presence of the restricting ties) to show trends of retractor muscles. Note especially the much shorter and wrinkled hemipenial body and the irregular sulcus spermaticus in the "T-shaped" organ, both of which are caused by the restricted retractor muscles.

shaped condition" is: an artifact of technique. The "Y-shaped condition" reflects the morphology of a better-prepared hemipenis.

Although hemipenis morphology is a valuable taxonomic feature of snakes, the proper preparation of everted hemipenes is a difficult process that requires some experience and skill. Most field-

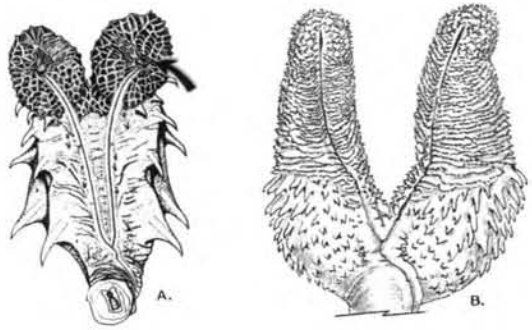

FIG 2. Zaher (1999: 15) noted that the drawing of the hemipenis of *Trimeresurus stejnegeri* presented by Mao et al. (1984) (A) differed from that of vipers in general by having much shorter apical lobes. As shown by the disappearance of the forks of the sulcus into the apparent middle of the lobes (arrow), they are incompletely everted. A drawing of the hemipenis of *Crotalus horridus* (HGD-HISS 897; AMNH [Amer. Mus. Nat. Hist] 97641) is provided for comparison (B).

everted hemipenes are incompletely everted. The preparation is best done on freshly killed specimens, although, with considerable effort, it is possible to evert the hemipenes to some degree from museum material (Pesantes 1994).

The critical element of preparation pertinent to the present discussion is that the skin of the tail must be slit on the ventral midline for a short distance (~2–3 subcaudals) from the cloaca to the point(s) of attachment of the retractor muscle (*m. retractor penis magnus*) to the inverted hemipenis. For proper eversion of the hemipenis, the retractor muscles must then be cut in two. The attachment of the muscle to the tip of the hemipenis is single in those taxa with cylindrical or slightly bilobed organs (e.g., *Coluber, Elaphe*), but in those with extensive bilobation (e.g., viperoids, most xenodontids) the retractor muscle is divided at some point to attach to the end of each of the two lobes. In these snakes the retractor muscle must be cut between the end of the hemipenial lobe and the point of division of the muscle. If this element of the procedure is neglected (cutting the retractor muscle too far posteriorly—or not cutting it at all) the divided retractor muscle will form a loop in the "lobular crotch" between the two lobes of the hemipenis. This will impede the complete eversion of the lobes, thus giving them a false appearance.

But the "T-shaped" figures shown by Zaher and Prudente (upper drawings in their Figs. 1 and 2) also demonstrate the distortions caused by an additional problem in executing proper hemipenial eversion. Not only does the internal loop of the retractor muscle restrict eversion of the lobes, but also when thread was tied at the base of the hemipenis to preserve the pressure of the fluid injected to inflate it, the retractor muscle was inadvertently tied in and bound to the base. The short and convoluted hemipenial body and the distortion of the sulcus spermaticus in the "T-shaped" figures are clear indications that the retractor muscle was included in and restricted by the tied base. Although the problems resulting from this may not be apparent during the process of preparation, they become visible later when the action of the preservative causes the retractors to shrink, thus distorting the lengths and shapes of the external hemipenial membranes (Fig. 1). No matter how much pressure is exerted on the injected preservative, the muscles resist and the entire organ gradually curves over toward the sulcate side.

This was the case in the beautiful (but unidentifiable) drawing of the hemipenis used in the description of the xenodontid genus *Psomophis* Myers and Cadle (1994: Fig. 3). My reexamination of the specimen drawn (USNM 331437) showed the hemipenis to be far from "fully everted," and so badly distorted that the drawing showed an apical (rather than a sulcate-side) view of the partly-everted lobes. The relationships of *Psomophis* cannot be determined from this drawing.

This is not a new problem in hemipenis descriptions, or one unique to Zaher and Prudente or to Myers and Cadle. Among many errors in the literature, I will describe only two, one of which is mine.

(1) The hemipenis of *Trimeresurus stejnegeri* was depicted by Mao et al. (1984: Fig. 6) as having the apical lobes much shorter than the hemipenial body. In contrast, the hemipenis of *T. stejnegeri* was described by Pope and Pope (1933) as "extending to 13–14th [sub-] caudal plate, forked opposite 7–8th," e.g., having long hemipenial lobes. The difference between the two descriptions is explained by the "disappearance" of the sulcus in the middle of

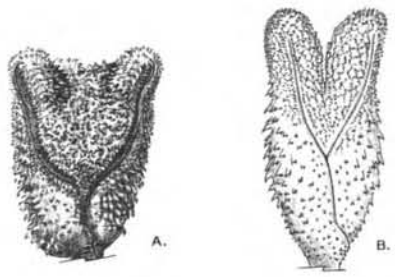

FIG 3. The hemipenis of *Philodryas olfersi*: (A) UMMZ (Univ. Michigan Mus. Zool.) 108988 as shown in Dowling (1969); (B) as drawn in 1971 (HGD-HISS; AMNH 88587). It is notable that A was noted to be 8 SC (subcaudals) in length, whereas B was recorded as 12 SC.

the lobes in the figure presented by Mao et al. This feature shows that the hemipenial lobes are incompletely everted, due to the restriction of the divided retractor muscle (Fig. 2).

Zaher (1999: 15) had mentioned this figure as being in contrast to the general rule that viperids have hemipenial lobes "two or more times longer than the hemipenial body." Rather than *T. stejnegeri* having a different hemipenial morphology, however, it is the drawing that is in error because of incomplete eversion of the organ.

(2) My own major entry into errors of description is the "correction" of previous figures of the hemipenis of *Phylodryas olfersi* (Dowling 1969). As shown here (Fig. 3), the "correction," although in the right direction, is far from an accurate depiction of the fully-everted hemipenis.

I must admit that it took me many years to recognize these problems and to determine their solution. Thus, they are not mentioned in the early paper by Dowling and Savage (1960), and sadly, many of the "beautiful and detailed drawings" done for me in late 1960s and 70s I now recognize to be of incompletely everted organs (Fig. 4).

The above corrections and comments do not affect Zaher and Prudente's (1999) relegation of *Tripanurgos compressus* Fitzinger (1843:27) to the synonymy of *Siphlophis* Fitzinger (1843:27). They appear to be correct in this decision—and it has the additional benefit of deleting two more monotypic genera from the Neotropical snake fauna.

FIG 4. Incomplete and irregular hemipenis drawings from the Dowling (HISS) collection (1969–1973). A. *Conophis vittatus* AMNH 66337: Apical discs omitted (*fide* Auth et al. 1998). [Also true of Zaher 1999: Fig. 41, upper. Photo of same specimen.] B. *Hydrops martii*, AMNH 36161: Distal lobes inverted (cf. Zaher 1999: Fig. 52, upper). C. *Phyllorhynchus browni*, UMMZ 58386: Distal lobes inverted (personal observation).

Acknowledgments.—I thank Janann Jenner for her sketches of the hemipenes and for her discussion of and critical comments on the manuscript.

A Re-Evaluation of the Evidence for a Mid-Pleistocene Mid-Peninsular Seaway in Baja California: A Reply to Riddle et al.

L. LEE GRISMER
Department of Biology, La Sierra University
Riverside, California 92515-8247, USA
e-mail: lgrismer@lasierra.edu

Riddle et al. (2000) utilize mitochondrial DNA (mtDNA) sequence data from *Bufo punctatus* and five rodents to construct intraspecific gene phylogenies (phylographies) in order to test historical biogeographical scenarios proposed for the herpetofauna of Baja California by Murphy (1983), Grismer (1994), and Upton and Murphy (1997). Riddle et al. (2000) test a late Pleistocene through Holocene dispersal model and a late Neogene vicariance model, noting that each should have a signature phylogeography: the dispersal model should show widely distributed species with little or no genetic differentiation among populations from different regions whereas the vicariance model should show (given that enough time has emerged) reciprocally monophyletic phylogroups (groups of closely related individuals) on opposite sides of a presumptive barrier, either historical or contemporary. They present their results as a series of area phylograms which display intriguing patterns of organismal relationships, and note that all six species exhibit multiple geographically separated phylogroups. However, their analyses are not fully explanatory, segments of their results allow for multiple interpretations, and alternate hypotheses remain unaddressed.

Riddle et al. (2000) note that there are separate northern and southern peninsular phylogroups in all five rodents with divergences ranging from 1.8 to 4.1%. They attribute this to a mid-Pleistocene transpeninsular seaway. For four of these species, a mid-peninsular vicariant model appears to be the most parsimonious hypothesis.

In support of their hypotheses, Riddle et al. (2000) utilize published data from additional reptiles which include *Pituophis vertebralis* (Rodríguez-Robles and de Jesús-Escobar 2000), *Petrosaurus repens* (Aguilar-S. et al. 1988), *Urosaurus nigricaudus* (Aguirre-L. et al. 1999), and *Uta stansburiana* (Upton and Murphy 1997). It is here I believe alternate hypotheses exist. Riddle et al. (2000) state that genetic structuring in all these species is consistent with a mid-peninsular vicariant event, even though their own criteria of reciprocal monophyly is met in only one of those species, *Uta stansburiana* (Upton and Murphy 1997). Regarding *Pituophis vertebralis*, Grismer (2001) demonstrated that its phylogeographic relationships (Rodríguez-Robles and de Jesús-Escobar 2000; Fig. 5b), were consistent with a dispersal-based model, and Rodríguez-Robles and de Jesús-Escobar (2000) stated that their data did not unequivocally support a mid-Pleistocene vicariant event. Three of the five allozyme character states listed on the tree of *Urosaurus nigricaudus* (Aguirre-L. et al. 1999: Fig. 2) were incorrectly mapped (compare their Fig. 2 with Table 3 for sAat-A, Pep-A^2, Pep-B^2) and thus, do not support a mid-peninsular vicariant event. Additionally, one of the population samples of *Urosaurus* was the genus *Uta* (see Grismer 2000a) which further confounded the results. For *Petrosaurus repens* (Aguilar-S. et al. 1988), Augirre-L. et al. (1999) indicate that these data are not consistent with a mid-peninsular seaway. Additional molecular data sets (allozymes and/or mtDNA) from five other lizards having transpeninsular distributions (*Sauromalus ater* [Petren and Case 1997]; *Callisaurus draconoides* [Adest 1987]; *Sceloporus zosteromus* [Grismer and McGuire 1996]; *Cnemidophorus hyperythrus* and *C. tigris* [Radtkey et al. 1997]), one other snake (*Chilomeniscus cinctus* [Wong et al., in prep.]), and one frog (*Bufo punctatus* [Riddle et al. 2000]) show no significant statistical support in their respective trees that are consistent with a mid-peninsular vicariant event.

Riddle et al. (2000) provide support for the previously hypothesized (Grismer 1994; Murphy 1983) northern Gulf and Cape Region vicariant events in three species with divergences of 7.5–8%. They purport that these events occurred approximately three million years ago (mya) and following Upton and Murphy (1997), suggest that the mid-peninsular vicariant event occurred approximately 1 mya. At 1 mya, the geomorphology of the peninsula was essentially the same as it is today: all mountain ranges had reached their current altitude, the Gulf of California had receded to its current position as a result of the uplift of mountains in southern California, and fluvial deposits from the Sierra de la Giganta had created a land positive connection with the Cape Region and the rest of the peninsula (Gastil et al. 1975, 1983; Stock and Hodges 1989). Sea levels, however, fluctuated greatly (Everenden and Everenden 1970) which would be the only way by which a mid-peninsular seaway would have formed. However, for a seaway to cross any portion of central Baja California during that time period or later, it would have had to have risen at least 300 m in elevation above its current level. This would have re-inundated most of southeastern California (portions of which are currently below sea level) and the Isthmus of La Paz, which reaches 10 m above sea level at its highest point. Geological evidence for mid-Pleistocene re-inundations of this magnitude do not exist. Furthermore, based on the current distribution of various phylogroups (Murphy 1983; Riddle et al. 2000; Upton and Murphy 1997), the location of this presumptive mid-peninsular seaway has ranged 360 km, from near Puertecitos to near Loreto. Riddle et al. (2000) had to infer the age of this proposed seaway from Upton and Murphy (1997) and from the percentage of sequence divergence in the taxa they examined because there is little geological evidence in support of this seaway's age, location, or existence. However, the data from other authors are not in wholesale agreement, placing the age of this alleged seaway at one million (Upton and Murphy 1997) to 13.2 million years (Rodríguez-Robles and Jesús-Escobar 2000).

Despite the various interpretations of age and location of this hypothesized seaway, Riddle et al. (2000) have made a valuable contribution to the biogeography of the terrestrial vertebrates of Baja California in supporting previously proposed hypotheses. Their interpretation of the mtDNA analyses highlights the important concern that unrecognized vicariant events may be embedded within intraspecific phylographies of widely distributed species (Grismer 2000b). However, they overstate this by noting that "sole-reliance on species level taxonomy...has obscured...biodiversity" even though Grismer (1994) utilized the intraspecific relationships of 15 species in hypothesizing some of the same scenarios that Riddle et al. (2000) discuss and support. As for the presence of a

mid-peninsular seaway, both the geological and biological data are still unclear as to when, where, or even if it occurred.

An alternate hypothesis for the mtDNA patterns observed in a number of species from central Baja California may involve the abrupt change in habitat and weather patterns that occur in central Baja California. In the vicinity of San Ignacio, which is almost exactly one-half of the way down the peninsula, the Vizcaíno Phytogeographic Region of the north changes into the Magdalena Phytogeographic Region of the south (Wiggins 1980). Geographically concordant with this transition is the transition of a granitic substrate in the north to a volcanic substrate in the south (Grismer 1994). Lastly, this area is the general southern limit of northern winter storms and northern limit of southern summer storms (Turner and Brown 1982). These three major environmental factors all converging in central Baja California may have contributed to the genetic substructuring currently observed. However, the mechanisms by which such events would promote reciprocal monophyly in phylogroups are not obvious. Clearly, more genetic studies of transpeninsular taxa and geological studies of the tectonic history of central Baja California are warranted before any sound hypothesis is to emerge.

Forest for the Frogs, Frogs for the Forest

KYLE SUMMERS

The alarming pace with which the rainforests of the neotropics (among other places) are disappearing is well known (Laurance and Bierregaard 1997). The adaptation of populations to specific habitats, as well as historical and geographic contingencies, ensure that different patches of rainforest often support different species or subspecies (Terborgh 1992). This, in part, is responsible for the extremely high biodiversity associated with the neotropical rainforests, and the dramatic loss of diversity associated with deforestation. Certain representatives of the exquisite beauty and diversity of lifeforms in the neotropical rainforests have become symbols recognized worldwide, such as the toucan and the *Heliconius* butterfly. Poison frogs of the family Dendrobatidae have also become icons of the neotropical rainforests. One can hardly walk into a gift shop without seeing postcards and posters depicting these small but beautifully colored frogs. Plastic models, puzzles, and many other toys representing these frogs have flooded the U.S. and European markets. At the same time, there has been an explosion in interest on the part of hobbyists to keep these frogs in terraria. Their beautiful coloration, combined with complex behavioral repertoires that can be easily observed in captivity, make them very popular as pets. This popularity has unfortunately led to frequent illegal collection and trade of poison frogs on the pet market.

In my research on a number of species of dendrobatids, I have worked in several localities where the abundance of these frogs appears to have been negatively affected by the activities of illegal collectors. In talking to local residents, it is not uncommon to hear

them say they have been employed by "gringos" (usually from the U.S. or Germany) to find frogs, which were then placed in small containers (such as film canisters), an obvious sign that the frogs were to be smuggled out of the country. In recognition of this problem, these frogs are included on CITES lists and their collection and sale is regulated. In spite of this, illegal collection and trade is alarmingly common.

Recognition of this problem among hobbyists has led to admonitions to buy only captive-bred frogs. This response is admirable, but unfortunately it has not resolved the problem of illegal collecting and trading, and captive breeding brings its own problems as well. For example, captive breeding of poison frogs is a difficult enterprise for many species, and the occurrence of nutritional problems, such as spindle leg disease, and of pathogenic infections, is all too common in captive populations (Heselhaus 1992). This problem is exacerbated by the small population sizes of captive breeding colonies, which may lead to a reduction in genetic diversity (Templeton et al. 1996) and an increase in problems associated with the lack of such diversity (Barrett and Charlesworth 1991; Gabriel et al. 1994).

Recently, Rainer Schulte, a biologist living in San Martin Province in central Peru, has been attempting to simultaneously address the problem of tropical deforestation and that of illegal trade in poison frogs. San Martin is a mountainous province spanning the transition between the high Andes and the lowland Amazonian rainforest. The complex topography of the region has apparently produced a high diversity of poison frog species and subspecific variants, including some of the most beautiful and expensive species. Schulte has developed a plan to save these frogs from extinction.

Schulte's idea is to engender the management and production of poison frogs in the very rainforests where they live. To do this, he is recruiting the people who live in the forest where the frogs occur. The main factor causing deforestation in the neotropics is not increasing urbanization, which is confined to restricted areas, but rather the colonization of large tracts of rainforest by impoverished subsistence farmers (Kahn and McDonald 1997). As new roads are cut into the forest, farmers move in and begin to convert the surrounding forest into fields for the production of crops such as plantain and manioc. Because rainforest soils rapidly become depleted once the original rainforest is removed, these farmers are forced to continually cut new swaths of land to grow new crops.

Poison frog management holds out the possibility of making pristine rainforest an economic asset to the people who live in the forest. With individual frogs of some species (such as *Dendrobates fantasticus*) commanding prices of as much as US$ 100–150 in the U.S. and Europe, these frogs represent a substantial untapped economic asset for poor Peruvians living where the frogs live. But in order to utilize these frogs as a sustainable natural resource, it is necessary to manage them in an ecologically sound manner. This requires maintaining their primary rainforest habitats. Schulte's management method is simple and employs materials available to even the poorest people. Poison frogs (particularly those of the genus *Dendrobates*, which includes the most sought after species) have an unusual mode of reproduction. Eggs may be laid in the leaf litter or on a leaf, but once they reach the tadpole stage they are transported on the back of a "nurse frog" (the male in most species) to small pools of water that form in leaf axils of bromeliads and other forest plants.

Reproduction and population density can be limited by the availability of pools (Donnelly 1989). Increasing the number of available pools leads to increased breeding activity, such that additional tadpoles are produced, at least in some species (Schulte 1997). Schulte increases pool density using artificial pools constructed from discarded plastic soda bottles. These artificial pools are readily accepted by the frogs and used to deposit tadpoles. Hence, by installing such pools in a rainforest plot, local people can obtain a steady supply of young, healthy frogs from the rainforest. Naturally, the adult frogs must not be collected or disturbed, and a certain percentage of the young frogs must be allowed to remain in the forest to provide the next generation of adults.

This management program allows the local people to earn a substantial income, while at the same time providing an economic incentive for them to preserve primary rainforest. Cooperative associations of local people can combine their rainforest plots and preserve substantial areas of rainforest in particular regions. The variation of each species from region to region makes it viable to carry out this program in many different localities. In Schulte's home region near Tarapoto, he has recently formed an association of some 25 local residents (ASPRAVEP), who together are managing an area of some 250 hectares of primary rainforest fragments. Schulte claims that ASPRAVEP can produce a sustainable yield of several hundred juvenile *Dendrobates* (particularly *D. imitator*, *D. variablis*, and *D. fantasticus*) each year, and higher numbers of juvenile *Epipedobates* (*E. bassleri*, *E. trivittatus*, *E. pongoensis*, and *E. hanheli*). Given the high prices commanded by these frogs in the U.S. and Europe, the income from their export and sale will substantially exceed the income these local residents can obtain by cutting the forest and farming the cleared land, thereby providing an incentive for them to preserve the tracts of primary rainforest under their care.

Recently there has been considerable debate concerning methods for the preservation of tropical biodiversity (Mooney 2000). Some researchers argue that the best approach is to set aside large tracts of land as parks that are managed by professional caretakers equivalent to park rangers in the U.S. (Terborgh 1999). Others argue that the best way to ensure the long term preservation of biodiversity is to involve local residents in management, and to provide economic incentives by allowing sustainable forms of use (Janzen 1996). At this point, the debate concerning the creation of large parks is academic in much of South America, as many countries do not have the resources to create new parks or the ability to effectively manage those already in existence (Kahn and MacDonald 1997). Much of the rainforest in the neotropics has already been divided into forest fragments that exist in a mosaic with farmland and residential areas, and this is likely to become more common in the future (Laurance and Bierregaard 1997). Hence it is critical to discover ways to encourage local residents to preserve remaining fragments.

Schulte's effort is similar to other projects that are attempting to return the economic benefits of preserving the rainforest to the people who actually live there. Another example is the creation of laboratory facilities in Panama for the analysis of plant samples to identify potentially important new chemicals for the pharmaceutical

industry. Todd Capson and Phyllis Coley, in collaboration with the Smithsonian Tropical Research Institute, are spearheading this project, in which Panamanians are trained to carry out important chemical assays (such as those for anti-cancer and anti-HIV properties). By identifying such properties before the plants (or plant extracts) are sold to the pharmaceutical companies, their economic value to the people of the country of origin is vastly increased. The recent development of an extremely potent painkiller from the toxins of a poison frog from Ecuador (Bradley 1993) highlights the benefits that the identification of potentially useful compounds from the tropical forest could provide to people from the countries of origin, if they are able to participate in the process of discovery.

Dyscophus insularis is one of three species in the endemic Malagasy genus *Dyscophus*, which together with the Asian genus *Calluella* forms the subfamily Dyscophinae (family Microhylidae). While *D. antongili* and *D. guineti* are exclusively known from humid eastern Madagascar, *D. insularis* is largely a species of the seasonal dry areas of western Madagascar. It was recorded from five western localities by Blommers-Schlösser and Blanc (1991): the type locality Antsohy near Trabouzy, Belo (type locality of the synonym *beloensis*), Tsimanampetsotsa and Soalala (localities of the type series of the synonym *quinquelineatum*; Soalala being the locality of the lectotype), and Ankarafantsika. Glaw and Vences (1994) added two additional records, Ambanja in the north-west (voucher specimen in Zoologisches Forschungsinstitut und Museum A. Koenig, Bonn: ZFMK 52757) and Kirindy in the west (based on personal communications; vouchers collected in 1995: ZFMK 59982–59984). Emanueli and Jesu (1995) recorded the species from the Tsingy de Bemaraha, Goodman et al. (1997) from the Vohibasia forest. One additional locality in Blommers-Schlösser and Blanc (1991) does not fit into this distributional pattern, namely Marojezy in the rainforest area of north-eastern Madagascar. This locality was based on specimens in the Muséum National d'Histoire Naturelle, Paris (MNHN) already mentioned by Guibé (1978).

In the MNHN collection, we located five specimens of *D. insularis* with the origin Marojezy (MNHN 1973.577–581). Altitude of the collecting locality is given as 1300 m in the catalogue (not 300 m as reported by Guibé 1978) and collecting date as 2 July 1972. In the catalogue, this series is immediately followed by nine specimens (MNHN 1973.582–590) from Ankarafantsika (Ampijoroa), collected on 5 February 1973. No information on the collector(s) is given. According to entry notes of J. Guibé available in the MNHN, the specimens belonged to a large series of microhylids from "Massif de Marojezy et autres lieux" which were collected by C. P. Blanc. The *Dyscophus* specimens had the provisional numbers 2084–2092 and 2094–2098 and are marked in the

notes with the locality information "region Ouest." In a second notebook containing a list of the provisional numbers, the whole series 2082–2092 and 2094–2118 (comprising also other species) are explicitly stated to originate from Ankarafantsika, collected on 5 February 1973. Apparently, the locality information Marojezy for *D. insularis* is thus an error that occurred when the specimens were catalogued. To evaluate further evidence on the locality of these specimens, we examined the respective vouchers in more detail.

All specimens of both series are very similar regarding their (good) state of preservation, fixation, external morphology, and coloration. MNHN 1973.578 is an adult female (SVL 52.8 mm) containing 1100 mature blackish oocytes of 1–1.2 mm diameter, indicating that at least this specimen was captured during the reproductive season. Examining stomach contents, we observed three conspicuous items present in specimens from both series: a) Remains of a large ensiferan orthopteran in MNHN 1973.581 (Marojezy) almost certainly corresponding to undetermined but better preserved prey items in MNHN 1973.585 and 586 (Ankarafantsika); b) In MNHN 1973.578 (Marojezy) we found three abdomina of a tenebrionid coleopteran which were identical to a remain in MNHN 1973.590 and to a completely preserved specimen in MNHN 1973.587 (both Ankarafantsika); the beetle was determined as *Parecatus machloides* (Tenebrionidae: Asidinae), a conspicuous form which we did not see in any other stomach of about 200 Malagasy frogs examined from different localities; c) Stomach of MNHN 1973.579 (Marojezy) contained remains of the ant *Aphenogaster swammerdami*, a species that was also found in MNHN 1973.586 and 1973.588–589 (Ankarafantsika). Stomachs of specimens of both series contained sand.

Dyscophus insularis is a species breeding in lentic water and is known mainly from open areas of sandy soils. The ant *Aphenogaster swammerdami* is a species limited to open areas and is very common in the western dry forest habitats, although it also can be found in disturbed and secondary grassland habitats in the eastern high plateau (BLF, unpublished data). Marojezy is a mountain massif largely covered by primary rainforest; only above 1800–2000 m altitude the forest is replaced by open ericoid heathlands (Raselimanana et al. 2000). The MNHN *Dyscophus* specimens from Marojezy are reported as originating from altitudes of 1300 m (MNHN catalogue) or 300 m (Guibé 1978), which are covered by forest. It is very unlikely that this information is correct, considering the habitat preferences of *D. insularis* and its prey *A. swammerdami*. Furthermore, it also is not probable that an explosive breeder like *D. insularis* would reproduce in the cold and dry season (July) as suggested by the presumed collecting date and the oocytes found in MNHN 1973.578. The intensive surveys of Raselimanana et al. (2000) failed to record *D. insularis* from Marojezy, despite the use of pitfall trapping which is suited for the capture of terrestrial microhylids. Considering also the conspicuous agreement between stomach content composition, there is overwhelming evidence that the Marojezy entry in the MNHN catalogue is erroneous, and that the respective *D. insularis* specimens belong to the same series as MNHN 1973.582–590 and were thus collected at Ankarafantsika.

This removes one anomalous biogeographic pattern in the distribution of Malagasy anurans. It also stresses the endemism of the amphibian fauna of western Madagascar, and bears relevance for conservation. If *D. insularis* is not present in the Marojezy reserve, it is currently known from only three officially protected areas, namely Ankarafantsika, Tsingy de Bemaraha, and Tsimanampetsotsa (although its occurrence within the boundaries of the latter reserve are still to be confirmed).

Acknowledgments.—We acknowledge the help of Claude Girard (Paris) who determined the tenebrionid specimens, and Alain Dubois and Annemarie Ohler (Paris) who allowed dissection of specimens held in their care.

The Western Ghats region of India has been identified as one of the 18 biodiversity hot spots of the world (WCMC 1988), and harbors 205 species of amphibians (Daniels 1992). *Kaloula pulchra* is a medium-sized burrowing frog (mean male SVL = 67.3 mm, N = 10) distributed in parts of Western Ghats. Although *K. pulchra* is a common microhylid of this region, we have limited knowledge about this species from the Western Ghats. In particular, very little is known about its reproductive biology. We investigated the

breeding period and advertisement call of this species.

Both field observations during the breeding season and characterization of the male call parameters were conducted near Dharwad (15°27′N, 75°05′E). From 1989 to 1997, we recorded male calls with directional microphones (AKG, D- 707/190 C, D- 1000 I) and tape recorder (AKAI AJ 490 FS, 4.8 cm/s) at water temperatures of 19–21°C and relative humidities between 90 and 93%. We used a LUTRON SL 4001 SPL meter (fitted with Bruel & Kjaer multi-function acoustic calibrator, 4226) to measure the sound pressure level (re 20 μPa, "fast" root-mean-square [RMS], C weighing) from a distance of 1 m. Calls of 20 males were analyzed by the acoustic analyzer computer program MOSIP® spectro analysis V6 8, 41/89, MEDAV GmbH, at Zoological Institute, University of Bonn, Germany; statistical analysis was carried out with Statgraphics (STSC, Statistical Graphic Corp., Knoxville, Tennessee, USA).

Calling activity began after the first two to three heavy pre-monsoon showers (April/May) during 1990, 1991, 1992 and 1996. When the pre-monsoon rains failed to occur during 1993, 1994, 1995, and 1997, the calling began with the onset of monsoon rains (June/July) and continued until August. Observations over a period of eight years indicated that the males emit the advertisement call from April to August. During the same period amplected pairs also were observed in the field. Hence, in the absence of reports on the gonadal cycles, we suggest that April to August may be the breeding period of *K. pulchra*. The calls were given while males floated on the water surface. Calling was in chorus, however adjacent calling males alternated their calls (N = 50). Advertisement calls were emitted in series with variable call intervals. Each call occurred in a single pulse group of 28–56 pulses (mean ± SE, 42 ± 1; Fig. 1A) and the number of pulses per second varied between 54 and 114 (mean ± SE, 84.2 ± 6.1). The pulse interval was very short and could not be recorded. The amplitude varied slightly from call to call (Fig. 1B). The call began with a pulse of low amplitude and reached the maximum after the 6th to 10th pulse (Fig. 1A). Subsequently it decreased gradually. The call duration, call interval, and the call period varied from 318 to 932 ms (mean ± SE, 579 ± 14; N = 20), 207 to 1078 ms (mean ± SE, 541 ± 27; N = 20) and 797 to 1672 ms (mean ± SE, 1140 ± 31; N = 20), respectively. The frequency spectra ranged between 50 and 1760 Hz with two bands (Fig. 1C). The dominant frequencies were between 400–1220 Hz (mean ± SE, 704.8 ± 85.1; N = 10). The sound pressure level measured from a distance of 1 m from the frog varied between 54 and 60 dB.

The advertisement calls of breeding male anurans have two main functions: a) intrasexual competitive interactions for calling stations, which in some species are also oviposition sites, and for active (acoustic) space; and b) intersexual attraction of mates (Littlejohn 1977). Additionally, calling sites and call parameters may reflect mechanisms for reproductive isolation among species. Acoustic communication studies in Western Ghat microhylids are limited to *Microhyla ornata* (Hiremath 1991), *M. rubra* (Kanamadi et al. 1994), *Ramanella variegata* (Kanamadi et al. 1993), and *R. montana* (Kadadevaru et al. 1998).

Kaloula pulchra, R. variegata, M. ornata, and M. rubra are sympatric microhylid species at Dharwad. Calling sites of *M. rubra* are on land in open fields near water bodies (Kanamadi et al. 1994), whereas those of *M. ornata* are depressions in muddy areas, and

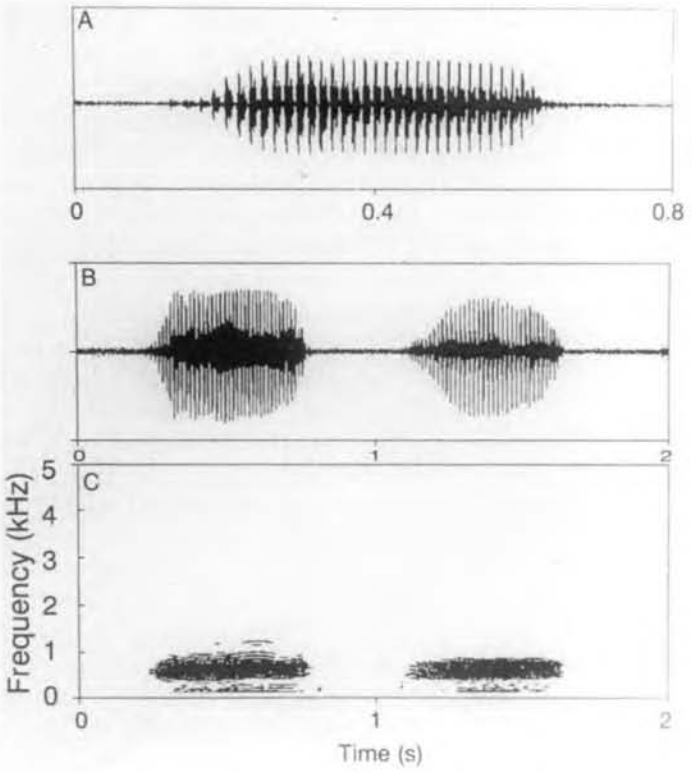

FIG. 1. (A) Oscillogram of a single advertisement call of *Kaloula pulchra* (66 mm SVL) showing amplitude modulation. Oscillogram (B) and sonagram (C) of two advertisement calls of *K. pulchra* (66 mm SVL) showing call interval and frequency spectra respectively. Recorded in Dharwad, India. Water temperature 20°C.

also in spaces under the grass (Hiremath 1991). The advertisement call of *M. rubra* consisted of 66–135 pulses/s (mean ± SE, 108 ± 2.4; N = 39). The call duration varied from 138 to 228 ms (mean ± SE, 168 ± 3.2; N = 39) and the number of pulses ranged between 15 and 21 (mean ± SE, 18.0 ± 2.4; N = 40). In *M. ornata*, the advertisement call comprised 33–40 pulses/s (mean ± SE, 30.0 ± 0.3; N = 28). The call duration varied from 13 to 77 s (mean ± SE, 33.2 ± 5.3; N = 14) and the pulse number ranged between 10 and 14 (mean ± SE, 12.8 ± 0.30; N = 28). Males of *K. pulchra* call from the surface of water bodies, similar to those of *R. variegata* (Kanamadi et al. 1993). It is likely that the different calling sites of *M. rubra* and *M. ornata* contribute to spatial separation of these sympatric species from *K. pulchra* and *R. variegata.* The advertisement call of *R. variegata* consisted of 359–385 pulses/s (mean ± SE, 369 ± 4.6; N = 5). The call duration varied from 187 to 234 ms (mean ± SE, 214 ± 3.6; N = 10) and the pulse number ranged between 74 and 137 (mean ± SE, 96 ± 5.6; N = 11). Its frequency spectra ranged between 300 and 4300 Hz with harmonics and a distinct fundamental frequency (Kanamadi et al. 1993). In the present study of *K. pulchra*, the pulse number (28–56) and the frequency range (50–1760 Hz) are much lower. Although males of both species share common calling sites, the species-specific pulse number and the variation in the frequency range may help in attracting conspecific females.

The call duration of *K. pulchra* from Thailand (Heyer 1971) ranged from 560 to 600 ms, consisted of 32–35 pulses/s with 18–21 pulses/call, and the frequency spectra had a dominant band at 250 Hz. Our study of the same species shows differences in the

call duration, pulses/s, pulses/call, and the frequency range. The differences in the call parameters may reflect geographic variation, as described in *Rana ridibunda* (Schneider 1973; Nevo and Schneider 1983; Kuhn and Schneider, 1984; Schneider and Sofianidou 1985), *Bombina orientalis* (Akef and Schneider 1985; Schneider et al. 1986), and *M. ornata* (Hiremath 1991).

Acknowledgments.—The study was supported by a grant from Department of Science and Technology (No. SP/SO/C-23/93) awarded to R.D.K. and partly by the Special Assistance Program –II grant, funded by University Grants Commission (UGC), New Delhi. We also thank UGC, New Delhi, India and German Academic Exchange Service, Bonn, Federal Republic of Germany, for selecting the first author for study visit (1997).

Seasonally Skewed Sex-Ratios of Road-Collected Texas Horned Lizards (*Phrynosoma cornutum*)

WADE C. SHERBROOKE
Southwestern Research Station

P.O. Box 16553, Portal, Arizona 85632, USA
e-mail: wcs@amnh.org

Road surfaces, paved and nonpaved, are modern landscape features that have been utilized by herpetologists for collecting for decades (Klauber 1939). In the case of snakes, both their positive thermoregulatory features and their negative dead-on-road (DOR) aspects are well appreciated, the latter having conservation implications (Rosen and Lowe 1994; Rudolph and Burgdorf 1997; Rudolph et al. 1999). Less is known about the effects of roads and their adjacent landscape features on lizard behavior and survival. For example, roadside features may influence harvester ant populations (DeMers 1993), which are an important food of *Phrynosoma* spp. (Pianka and Parker 1975).

Fair and Henke (1997a) evaluated methods of collecting *P. cornutum* in southern Texas (including roads). Henke and Montemayor (1998) presented evidence of seasonal and diel use patterns of roads by this species in southern Texas. They did not comment on sex ratio. In their study area of sparse vegetation the sex ratio did not deviate from 1:1 female/male (Henke and Montemayor 1998; S. Henke, pers. comm.). Vegetative habitat characteristics can affect horned lizard abundance and foraging activity (Whiting et al. 1993; Fair and Henke 1997b).

Here I present evidence that in Texas horned lizards (*Phrynosoma cornutum*), a threatened species in Texas (Price 1990; Donaldson et al. 1994), the sex ratio of lizards occurring on roads along the Arizona and New Mexico border is seasonally skewed. In interpreting these data, I hypothesize that seasonal use of roads as a landscape feature by Texas horned lizards is related to their mate-seeking behavior, and because of vehicle-caused mortality this behavior may contribute to local and regional extirpation.

The range of Texas horned lizards encompasses much of the Chihuahuan Desert, shortgrass prairies, and desert grasslands of western North America (Price 1990) where it may encounter dense desertshrub and grassland communities (Brown 1982). Between 1983 and 2000 (18 years), 452 Texas horned lizards were collected on paved road surfaces in southeastern Arizona (Cochise Co.) and southwestern New Mexico (Hidalgo Co., a few from Grant Co. and Luna Co.). Most lizards were collected during a morning drive (0800–1200 h), traveling at about 60 kph from Portal, Arizona, east to New Mexico Highway 80, north to New Mexico Highway 9, east to Animas and then to the Playas Valley, then south to the Playas Smelter (Phelps Dodge Corporation) and/or north on New Mexico Highway 113 to Interstate Highway 10, and then back to Portal (210 km). Road cruising conditions allowed easy identification of Texas horned lizards on the road well before they could flee, including possible juveniles (many additional captures were of the smaller species *Phrynosoma modestum*). Capture rate of lizards seen on the roadway was very high, >95%, both those "freezing" on the road surface and those running off the road into

TABLE 1. Seasonal sex-ratios (F = female, M = male), by 15- and 16-day half-month periods, of road-collected adult Texas horned lizards (*Phrynosoma cornutum*) in Arizona and New Mexico, 1983–2000. Collection effort was not equal throughout the months.

Month	April	May	May	June	June	July	July	Aug	Aug	Sept	Sept	Nov
Days	16–30	1–15	16–31	1–15	15–30	1–15	16–31	1–15	16–31	1–15	16–30	1–15
N = F/M	0/1	6/14	32/178	21/137	10/15	7/0	1/1	1/0	1/1	7/2	4/1	1/0
ratio F/M	—	1:2.33	1:5.56	1:6.52	1:1.5	—	1:1	—	1:1	1:0.29	1:0.25	—

adjacent vegetation where they stop and "freeze." Seasonal abundance of lizards on highways facilitated collecting for behavioral and other studies. Most lizards were later released at sites of capture or placed in Southwestern Research Station collections.

Location, date of capture, sex, mass (g), and snout-vent length (SVL, mm) were recorded. The prime collecting time was late May (16–31) and early June (1–15), 81.4% of lizards collected (Table 1), when effort was maximal in terms of number of collecting days and kilometers driven. For analysis, lizards were grouped into adults and juveniles, and into 15 or 16-day (half-month) capture periods throughout the collecting season (Table 1). Most animals were adults (≥ 68 mm SVL), N = 438, 96.9%; 14 juveniles (≤ 67 mm SVL) comprised 3.1% (for size of adults see Ballinger 1974 and Howard 1974). Snout-vent lengths of juveniles were (May 1–15) 36 mm, (May 16–31) 37, 39, 54, 66, 67 mm, (June 1–15) 40, 47, 53, 57, 58 mm, (June 16–30) 56, 62 mm, (August 16–31) 65 mm. All were above hatchling size of about 17–25 mm SVL (Blaney and Kimmich 1973; Burrow 2000; WCS, pers. observ.). Juveniles were not included in the sex-ratio analysis.

For each 15- or 16-day collection period the number of females and males, and the female-to-male sex ratio are presented (Table 1). During the one-month period (May 16–June 15) 368 adult lizards were collected, 14.4% female and 85.6% male: males were 85% of road-collected lizards in the May 16-31 period and 87% in the June 1–15 period. During this month the female/male sex ratio was close to 1:6. This period encompasses the peak of the mating season (Ballinger 1974; Howard 1974). Immediately before (May 1–15; N = 20) and immediately after (June 16–30; N = 25) the male preponderance was much less, female/male 1:2.3 and 1:1.5 respectively. In contrast to May 16–June 15, during the three-month post-mating-season of July 1–September 30, when 26 lizards were collected, the sex ratio became highly skewed in favor of females, 1:0.24 (females 80.8% and males 19.2%). Egg laying occurs in July (Sherbrooke 2000; Sherbrooke, unpubl. data for 2000, three additional nestings). Females may increase movement activities while seasonally searching for appropriate nesting sites (Burrow 2000; WCS, pers. observ.).

The seasonal switch in sex ratio suggests that the skewed male preponderance in late May and early June is not because of a population-based sex ratio that differs from 1: 1, in agreement with reports from other areas (Whiting et al. 1993; Henke, see above). One explanation for the May 16–June 15 skewed sex ratio is that males, possibly seeking mates by increasing movement, encounter roads more frequently than do more sedentary females. Additionally, or alternately, males once encountering road surfaces may linger on open roads for extended periods of time. The result in both behavioral scenarios would be a male-bias sex-ratio in samples of road-collected lizards. I discount the possibility that sex differences in emergence times from hibernation is the causal factor for the sex bias; males and females in this area seem to emerge simultaneously between 19 April 1998 and 3 May 1998 (Sherbrooke, unpubl. data; N = 8). The difference observed in seasonal sex-ratios on roads between south Texas (1:1, see Henke above) and this study in Arizona-New Mexico (1:6) may be because of differences in populations of lizards, features of the landscape, or unidentified factors. Whiting et al. (1993) and Burrow (2000) noted that partially, versus densely, vegetated habitat facilitates locomotion, foraging, and thermoregulation in *P. cornutum*.

In Oklahoma, *Phrynosoma cornutum* males have been shown to travel greater distances than do females during the mating season (Stark 2000; Stark and Fox 2000). This seasonal behavior by males may explain the male-bias sex-ratio during May 16–June 15 in Arizona and New Mexico, but the second hypothesis that males remain on roads when encountered also could be valid. Although roads prove to have negative survival value (DORs), they might be attractive to male lizards because of the expanse they provide for visually locating females. Roads, in this sense, mimic positive features of natural landscapes such as open wash beds and other disturbed sites that provide expansive visual openings that may aid in mate location in desertshrub and grassland communities with dense vegetation where ground-level shrubs, grasses, and herbaceous plants inhibit visibility.

The size dimorphism in horned lizards, males smaller than females, may have evolved because smaller, early-reproducing males are more successful in finding dispersed mates (Zamudio 1998). Male horned lizards may have larger home ranges than females (Lowe 1954; Baharav 1975; Turner and Medica 1982), although perhaps not always (Burrow 2000). Although the lack of territorial defense and applicability of the term home range to the movement activities of Texas horned lizards has been studied and debated (Whitford and Whitford 1973; Munger 1984 a,b,c), it seems that males of this species may expand or abandon home ranges during the breeding season when they exhibit increased movement activities (Fair and Henke 1999; Stark 2000; Stark and Fox 2000). Munger (1984a) suggested that non-receptive females could modify movements so as to avoid contact with males seeking copulations. The duration of receptivity by females is unknown, but from captive studies it may be brief (Montanucci and Baur 1982). Perhaps non-receptive females seasonally avoid visually open areas.

If the male mate-seeking hypothesis to explain the seasonally-skewed sex ratio was true, and open vistas enhance encounters with females, one would expect to encounter pairs of lizards on the road during the mating season. During this study four pairs of

copulating *P. cornutum* were encountered: female/male, (1) 22 May 1984 (109/87 mm SVL); (2) 31 May 1992 (88/89 mm SVL); (3) 30 May 1994 (94/79 mm SVL); 7 June 1994 (92/78 mm SVL). In addition, two pairs of two males were found socially interacting on the road, presumably visually attracted to one another: male/male, (1) 23 May 1984 (85/84 mm SVL); (2) 28 May 2000 (90/87 mm SVL). The seasonal presence of these pairs of *P. cornutum* on roads is in agreement with the male mate-seeking hypothesis, but not conclusive. Also to be considered, once pairs find each other they may move off of road surfaces into adjacent vegetated landscapes during precopulatory-pursuit behaviors (Tollestrup 1981; Montanucci and Baur 1982; Sherbrooke 1988), thus reducing road encounters of pairs. Multiple mating of captive pairs of *Phrynosoma ditmarsi* (Montanucci 1989) and *P. douglassi* (= *P. hernandesi*) (Montanucci and Baur 1982) have been recorded. Nothing is known as to repeated copulations by pairs in the field, but an individual female *P. cornutum* mated following a first nesting, presumable mating a second time (Burrow 2000).

Henke and Montemayor (1998) noted an increase in breeding-season occurrence of lizards on roads in South Texas. They suggested this increase in activity was the result of mate-seeking behavior. Although the sex ratio in the road-encountered samples was not the same in Arizona-New Mexico and in South Texas, the conclusion as to the cause of increased activity is similar. The increased occurrence of lizards on roads is related to increased lizard movement through habitats because of mate-seeking behavior. In addition to this general seasonal factor, here I argue that during the mating season in areas where the sex ratio of highway-encountered populations is skewed in favor of males, 1) it is the males that are moving more, and 2) the males may linger on road surfaces because of the increased possibility of mate encounter. Alternately, females could avoid roads. These hypotheses, and others for explaining the seasonally-skewed sex ratios encountered, may be testable using radiotelemetry or other tracking methods (Stark and Fox 2000) to study microhabitat movements of male and female Texas horned lizards during the breeding season.

Fair (1995) documented vehicle-inflicted road deaths in areas of south Texas. Depending on road traffic conditions, the presence of *Phrynosoma cornutum* on roads during the breeding season (May 16–June 15 in this study) can lead to various levels of male-biased mortality. Although I have not specifically collected data on DORs, I estimate that observed DORs are equal to between 25% and 50% of the collected and reported live population on these sparsely traveled roads. These mortality estimates are potentially depressed by carcass removal from the highways by turkey vultures (*Cathartes aura*) and Chihuahuan ravens (*Corvus cryptoleucus*) (WCS, pers. observ.). Clearly there is a seasonally-elevated mortality on roads that is male-sex biased in Arizona-New Mexico.

In certain regions this seasonally-increased mortality may threaten the existence of local populations of *Phrynosoma cornutum* . I have not noticed obvious population decline over the 18 years. But in regions where landscapes are increasingly dominated by human activities, with dense networks of roads and intensive vehicular use, local road mortality may not be offset by immigration and resulting population declines then become one factor leading to local extinctions. Such a scenario of increasing human demographics may have contributed to the decline of Texas horned lizards in eastern and central Texas. Although other factors such as direct effects of introduced ants or the indirect effects of these exotic ants on native insect communities (Donaldson et al. 1994; Suarez et al. 2000), that are important to horned lizard feeding (Pianka and Parker 1975), may have played a role in the decline of Texas horned lizards.

Acknowledgments.—I thank the many individuals who assisted with the collection of animals involved in this study between 1983 and 2000: in particular T. Almaguer, C. J. Cole, D. Cruz, W. Marlor, G. A. Middendorf, III, K. Hurley, K. Romig, E. E. W. Sherbrooke, S. W. Sherbrooke, R. C. Sherbrooke, G. Sorg, B. Tomberlin, C. R. Townsend, M. Webster, M. Westphal, and numerous volunteers at the Southwestern Research Station. R. Stark provided access to data in an unpublished manuscript and in his M.S. thesis, E. C. Hellgren provided a copy of A. L. Burrow's unpublished M.S. thesis, and S. E. Henke provided data on sex ratio in populations from southern Texas (Henke and Montemayor 1998), a copy of W. S. Fair's M.S. thesis, and other publications. For reading and commenting on the manuscript, I am especially indebted to S. E. Henke, E. E. W. Sherbrooke, and R. C. Stark.

The sleepy lizard, *Tiliqua rugosa*, is a large scincid from southern Australia. Males have broader heads than females, a sexual dimorphism that may have resulted from selection favoring males with enhanced fighting ability (Bull and Pamula 1996). In spring, adults of this species usually form monogamous pairs that remain in close contact (males less than 1 m from females) with each other over eight weeks before mating (Bull et al. 1998). Although fights are infrequently observed, evidence has suggested that males fight over access to females. Bull (1990) observed nine cases of males fighting in over 11,000 random encounters with lizards over seven years. In six cases a female was observed nearby. Fights can last over fifteen minutes with each male biting the head and attempting to flip the other male over (Bull and Pamula 1996).

From September to November 2000, we followed the daily activity of 30 radio-tagged lizards (14 females and 16 males) in an area of chenopod shrubs and open grassland (34°06'S; 139°26'E), approximately 20 km north of Mt Mary in South Australia. The lizards were sexed based on morphometric differences (Bull and Pamula 1996) and the application of pressure behind the cloaca to evert the hemipenes in males.

A gravel road runs from south to north through one part of the study area. The five adult lizards involved in the following observations had all been resident in the area for at least the three previous years. The centers of the home ranges of two male lizards, A and B, were on either side of the gravel road although both home ranges crossed the road and overlapped. Male A (625 g, SVL 305 mm, head width 67 mm, jaw length 60 mm) to the west was slightly lighter than male B (670 g, SVL 305 mm, head width 66 mm, jaw length 60 mm) to the east. In early September we observed that male A had extensive new damage to scales across the head, lower jaws, and back. At that time adult female E (725 g, SVL 30.0 cm) was active within the home range of male A.

Two weeks later, on 19 September, female E moved across to the eastern side of the road and into the home range of male B. On the next afternoon, males A and B were observed fighting on the eastern road verge. When first observed there were extensive scuffle marks in the gravel, indicating that fighting had been ongoing for some time. They stopped fighting when they were approached. However, male A had already sustained additional damage from this new fight, to scales across the top of its head, to both sides of its lower jaw, and along its back and tail. The damage was extensive and bleeding was evident from all these areas. Lizard B had no external damage, but bruising and some bleeding were evident inside the mouth. Female E was found 73 m away 30 min after the

fight.

During daily radio-locations, female E was found within 30 m of male B over the next six days, but was never observed to be paired with that male. Other paired lizards in the area were commonly found in body contact or within 1 m of each other. After six days female E moved away from male B and back to the western side of her home range. Over the week following the fight, male A had moved further west, up to 300 m outside its previous home range and nearly 400 m from where the fight took place. A week later male A briefly re-entered the home ranges of female E and male B. No further interactions were observed but further damage to the scales of male A was evident. Male A remained to the west and out of the home ranges of male B and female E for the remainder of the season.

On 3 October, female E had again moved to the eastern side of the road, back into the home range of male B. But in that area, over the next seven days, she was recorded as closely paired with male C (540 g, SVL 30.5 cm, head width 60 mm, jaw length 57 mm). Male C was lighter than male B and had a smaller head. Male C was with female E on the morning of 10 October. In the afternoon of 10 October males B and C were observed in a very aggressive fight for about 15 min. This fight took place in a small depression (30 cm radius, 20 cm deep). Male B was found basking next to this depression at 0900 h that morning. When first observed the lizards were already fighting. Initially they were circling each other with the head of one lizard next to the tail of the other. After 5 min the fighting developed into a head-to-head conflict with each lizard biting the head, mouth, and body of the other. The larger male B inflicted extensive superficial damage and injuries to the scales on the head and body of male C. During this part of the fight it is probable that male C sustained a broken right mandible. This break was not detected until closer examination the next day so the exact timing is uncertain. The break, two-thirds of the way down the jaw line, resulted in a vertical displacement of 3 mm in the jaw line. After 12 min, the head-to-head fighting stopped and the lizards circled each other for about 2 min. Finally male B, in a short tussle, obtained a firm hold on the front left leg of male C. At this point male C broke off fighting and retreated into a small hole at the side of the depression. After a pause, male B pursued and strongly bit the tail of male C a number of times. Male B then moved off. Female E was located within 10 m of the site 3 min later.

The injured male C moved to a 20 cm deep, 15 cm diameter sinkhole about 100 m away from the fight site, but still on the eastern side of the road. It was found within 5 m of this hole over the next nine days. The mandible of male C had not set three months later. The lizard was eating at this time. Male C remained out of the home ranges of male B and female E for the rest of the breeding season. Male C was alive eight months later. After the fight, female E initially moved into the same area as C, but within four days (14 October) had moved over 400 m, returning to the western side of the road and to its original home range. Male B also moved across the road into this area, although the two lizards were not observed together at any time during this period. Six days later (20 October) male B had moved 200 m, back to the central home range area on the eastern side of the road.

On 23 October female E was found paired with another small male D (530 g, SVL 29.0 cm, head width 62 mm, jaw length 57 mm) on the western side of her home range. This pairing started late in the season at a time when some established pairs in the region had already mated and separated. At this time male D showed no evidence of scale damage. Female E was paired with male D over the next seven days, but on 26 October they had moved to the eastern side of the road. On 30 October at 1000 h, male D and female E were found paired on the eastern side, with male B 30 m away. At 1700 h male D was found 360 m away, by itself, back on the western side of the road. Since the morning observation, it had sustained significant damage to scales on both sides of its body, on its head, lower jaw, back, rump, belly, and three legs. Bleeding was evident from a number of these areas. No fight was observed, but male B had fresh bruising in the back of its mouth and had some new scale damage predominantly along its left side. Male B again appears to have been the aggressor in this instance. Male D remained out of the home ranges of male B and female E for the remainder of the study period.

Female E once again had moved back to the western side of her home range the next morning. Male B also moved over to the western side of the road. Again, no interaction or close contact was observed between these two lizards at this stage, and on 1 November, female E moved nearly 300 m to the east, across the road. On 6 November, male B and female E were found paired on the western side of the road and they were then found together on four occasions over the next three days. At the study site the mean date for pairs to first form was 29 September. The mean date for pairs to be last recorded together was 4 November. Thus, pairing started at the time most lizards in the area were mating and separating.

Most of the radio-tracked males formed monogamous partnerships with females over the period September–November, the usual pattern for this species (Bull 1988; Bull et al. 1998). Over the same period ten other males, among the 16 tracked, were found with freshly-damaged scales and bleeding from the head, indicating they also had been involved in recent fighting, although none as severe as those described above. There were also several other observations of two males circling each other, on one occasion watched by the female partner of one of them. Thus although fights were rarely observed, and apparently rarely reached intense levels, they seemed to occur relatively frequently among males during the time of pairing. A number of males in the study group have offset lower jaws. It is postulated that the cause of this may have been breakages sustained during fights. These observations support the suggestion that one function of monogamous pairing in the period before mating is for males to guard their female partners (Bull 2000). Results from fights involving male B suggest that large size and perhaps associated large head size help males win fights, as suggested by previous observations of sexual dimorphism in head size (Bull and Pamula 1996) and of smaller males being displaced from partnerships (Bull 1990).

However, in the case of male B it was not clear if the fights were over access to a female or over access to home range area. Male B apparently initiated and won disputes with three other males, but did not gain immediate access to the female partner of those males. The observations lead to two conclusions. First, there are occasional males in the population that are much more aggressive than other males. This is not necessarily a function of male size because other larger males were involved in fewer disputes.

Second, although defeated males in this study fled from the scene of the fight and from their female partner, females did not automatically pair up with the victor. The female appears to make choices. In this case, female E associated with three other males before finally pairing with the victorious male B, when most other pairs had already mated and split up.

It was unusual to observe aggressive interactions of other males. The low frequency of aggression in the population could be related to the long-term, stable pair bonds that are formed in this species.

Acknowledgments.—Our research was funded by the Australian Research Council and the School of Biological Sciences, Flinders University. We thank Ron and Leona Clark for allowing us access to their land, and use of the homestead at Bundey Bore Station. Dale Burzacott helped with the logistics of the field work and Karin Hegetschweiler helped with field observations.

Pulau Tioman is the largest island of the Seribuat Archipelago and lies 48 km off the southeast coast of Peninsular Malaysia in the South China Sea. It is approximately 22 km in length and reaches 11 km in width at its widest point near its southern end. Characterized by steep-sided mountainous terrain reaching over 1110 m in elevation, the island supports a lowland mixed dipterocarp forest on its foothills and hill dipterocarp forest above 300 m, with its coastline and low-lying periphery dominated by mangrove and coastal vegetative communities (Latiff et al. 1999). Exposed granitic outcroppings in the form of large boulders define much of the island's rugged topography and its hillsides are cut by a number of boulder-strewn, fast-flowing streams. Because of its significant topographical relief and concomitant environmental diversity, this small island supports a remarkably diverse herpetofauna with perhaps as many as 83 species: 1 caecilian, 20 frogs, 1 turtle, 24 lizards, and 20 snakes are now confirmed, with an additional frog, 6 lizards, and 9 snakes represented by unconfirmed sightings (Table 1).

Prior to the first comprehensive herpetofaunal reports for Pulau Tioman by Hendrickson (1966a, b), the only other treatments of this island's hereptofauna were Boulenger's (1912) record of *Dogania subplana*, Smith's (1930) listing of 12 species, and de Haas' (1949) record of *Rhabdophis chrysargos*. Subsequent to Hendrickson's (1966a, b) reports, an unpublished report by Day (1990) added 4 species of amphibians and 16 species of reptiles. The most recent comprehensive treatment was Lim and Lim (1999), who added two species of amphibians and two species of reptiles to Pulau Tioman, and Leong (2000) and Leong and Tan (2000), who added one amphibian and one snake, respectively.

Three of us (LLG, RAS, and HK) visited Pulau Tioman from 2 to 6 November 2000 to assess its potential to serve as a site for a summer course in field biology. It came as a surprise that we were able to observe and confirm an additional five species of lizards and three species of snakes (Table 1) based on such a short visit, especially in light of the amount of research done on this island throughout the last century (see Ng et al. 1999 for a review). We also report our observations of three additional species of lizards which we were unable to confirm with voucher photographs or specimens, and provide comment on the unconfirmed records of previous authors (Table 1). Indraneil Das identified all voucher photographs which have been deposited in the La Sierra University Photographic Collection (LSUPC).

NEW RECORDS AND CONFIRMED SIGHTINGS OF PREVIOUS AUTHORS

Cyrtodactylus quadrivirgatus (Marbled Slender-toed Gecko). Manthey and Grossmann (1997) reported this species as occurring on Pulau Tioman but referenced no specimen or voucher photograph. On 2 November at 1000 h, we observed a single specimen (LSUPC L3313–17) sitting on a leaf approximately 1.5 m above the ground along the cross-island trail from Kampung Tekek to Kampung Juara at an elevation of approximately 600 m in hill dipterocarp forest.

Gekko monarchus (Spotted House Gecko). On 2 November at 0800 h, we observed a single specimen (LSUPC L3073) sitting head down on the vertical surface of a large boulder approximately 1 m above the ground along the cross-island trail at an elevation of approximately 100 m in lowland mixed dipterocarp forest. On 4 November, we saw at least eight individuals on large boulders in lowland mixed dipterocarp forest on the beach 1 km south of Kampung Tekek. Two of the females observed were gravid.

Cosymbotus platyurus (Flat-tailed Gecko). On 2 November at 1200 h, we observed two adults and one juvenile 4–5 m above the ground on the trunk of a large tree (ca. 1.5 m diam) along the

TABLE 1. Checklist of the terrestrial herpetofauna of Pulau Tioman, Peninsular Malaysia.

Species	Comments
AMPHIBIANS	
Frogs	
Megophryidae	
Leptolalax gracilis	
Megophrys nasuta	
Bufonidae	
Ansonia tiomanica	
Bufo asper	
Bufo melanostictus	
Bufo parvus	
Pelophryne brevipes	
Microhylidae	
Chaperina fusca	
Kaloula baleata	
Kaloula pulchra	
Rhacophoridae	
Philautus aurifasciatus	
Philautus vermiculatus	Unconfirmed listing (Berry 1975)
Polypedates leucomystax	
Ranidae	
Limnonectes blythii	
Limnonectes hascheanus	
Rana cancrivora	
Rana chalconota	
Rana doriae	
Rana erythraea	
Rana hosii	
Rana signata	
Rana sp.	Possibly undescribed species (Hendrickson 1966b)
Apodans	
Ichthyophiidae	
Ichthyophis sp.	Unidentified larva (Lim and Lim 1999)
REPTILES	
Turtles	
Trionychidae	
Dogania subplana	
Lizards

Draco sumatranus	
Gonocephalus chamaeleontinus	
Gonocephalus grandis	
Uromastycidae	
Leiolepis belliana	Unconfirmed sighting (Day 1990)
Gekkonidae	
Cnemaspis kendallii	
Cnemaspis sp.	Formerly *C. nigridius* (Denzer and Manthey 1991)
Cosymbotus craspedotus	Unconfirmed sighting; this report
Cosymbotus platyurus	
Cyrtodactylus quadrivirgatus	Manthey and Grossman's (1997) unconfirmed record confirmed here
Cyrtodactylus tiomanensis	
Gehyra mutilata	
Gekko monarchus	Day's (1990) unconfirmed sighting confirmed in this report
Gekko smithii	
Hemidactylus frenatus	
Lepidodactylus lugubris	Confirmed new record
Ptychozoon kuhli	Unconfirmed sighting; this report
Scincidae	
Dasia olivacea	
Emoia atrocostata	Unconfirmed sighting (Hendrickson 1966a)
Lipinia surda	
Lipinia vittigera	Unconfirmed sighting (Lim and Lim 1999)
Lygosoma bowringi	Unconfirmed sighting; this report
Mabuya longicaudata	Manthey and Grossman's (1997) listing confirmed in this report
Mabuya multifasciata	
Sphenomorphus scotophilus	
Varanidae	
Varanus nebulosus	
Varanus salvator	
Dibamidae	
Dibamus cf. *alfredi*	Possibly an undescribed species (Day 1990)
Snakes	
Typhlopidae	
Ramphotyphlops braminus	
Pythonidae	
Python reticulatus	
Colubridae	
Ahaetulla prasina	
Boiga cynodon	Unconfirmed sighting (Day 1990)
Calamaria lumbricoidea	
Calamaria pavimentata	
Cerberus rhyncops	
Chrysopelea ornata	Unconfirmed sighting (Day 1990) see (Lim and Lim 1999)
Chrysopelea pelias	
Dendrelaphis caudolineatus	
Dendrelaphis formosus	
Dendrelaphis pictus	
Dryocalamus subannulatus	
Elaphe flavolineata	Unconfirmed sighting (Day 1990)
Elaphe porphyracea	Unconfirmed sighting (Day 1990)
Enhydris enhydris	
Enhydris plumbea	
Gonyosoma oxycephalum	Unconfirmed sighting (Day 1990)
Lepturophis albofuscus	

TABLE 1. Continued.

Liopeltis tricolor	
Lycodon effraenis	Unconfirmed record (Manthey and Grossman 1997)
Oligodon purpurascens	
Oligodon signatus	Possibly and undescribed species (Day 1990)
Psammodynastes pulverulentus	
Rhabdophis chrysargos	
Zaocys carinatus	
Elapidae	
Ophiophagus hannah	Unconfirmed sighting (Hendrickson 1966a)
Naja sumatrana	Unconfirmed sighting (Hendrickson 1966a)
Maticora intestinalis	
Viperidae	
Trimeresurus cf. *popeiorum*	See Lim and Lim (1999) for discussion

cross-island trail at an elevation of ca. 650 m in hill dipterocarp forest. All escaped before being photographed. On 5 November at 0130, one adult (LSUPC L5907–08) was observed on the wall of an outdoor restaurant in Kampung Tekek.

Lepidodactylus lugubris (Maritime Gecko). On 4 November at 1400 h, we observed a single specimen (LSUPC L5909–10) sitting head-up on a small tree approximately 2.5 m above the ground outside a store in Kampung Tekek, at the turn-off to the cross-island trail. At 1430 h we observed another individual approximately 3 m above the ground on a coconut tree in the coconut grove 1.5 km east of the cross-island trail turn-off. On 5 November at 1200 h, we observed an individual on the illuminated police station sign in Kampung Tekek.

Mabuya longicaudata (Long-tailed Sun Skink). Manthey and Grossmann (1997) reported this species as occurring on Pulau Tioman but referenced no specimen or voucher photograph. On 5 November at 1300 h and again at 1630 h, we observed several specimens (LSUPC L4004–07) sunning themselves on rocks and logs in a cleared grassy area along the banks of Sungai Air Besar in Kampung Tekek. All observations occurred at sea level.

Dendrelaphis pictus (Common Bronzeback Snake). On 2 November at 1530 h, we observed a single specimen (LSUPC S2781–82) on the ground along the cross-island trail at an elevation of approximately 250 m in lowland mixed dipterocarp forest.

Dryocalamus subannulatus (Malayan Bridle Snake). On 4 November at 2100 h, we observed one individual (LSUPC S2756–65) crawling horizontally on the vertical face of a large granitic boulder approximately 1.5 m above the ground. The boulder was part of a large outcropping situated below the canopy of lowland mixed dipterocarp forest on the beach 1 km south of Kampung Tekek.

Zaocys carinatus (Keeled Rat Snake). On 3 November at 1400 h, we observed one adult (LSUPC S2774–80) crawling on the forest floor along the cross-island trail at an elevation of ca. 500 m in hill dipterocarp forest.

In addition to our confirmed sightings, we add the sight records of *Cosymbotus craspedotus* (Frilly Gecko), *Ptychozoon kuhli* (Kuhl's Gliding Gecko), and *Lygosoma bowringi* (Bowring's Supple Skink) as unconfirmed reports. On 5 November at 1200 h, we observed a single *C. craspedotus* approximately 5 m above the ground on a coconut tree in the coconut grove at the base of the cross-island trail, 1.5 km east of Kampung Tekek. The specimen was approximately 60 mm SVL, and had a grayish ground color with three pairs of obscure dark paravertebral blotches. A fringe along the side of the body and a large fringe coming off the posterior margin of each hind limb were visible. The hands and feet were webbed and the anterior half of the tail was as wide as the body and the fringes were not crenulated.

At 1500 h at an elevation of approximately 600 m along the cross-island trail in hill dipterocarp forest, we observed (through binoculars) a single *P. kuhli* sunning itself head down on the trunk of a large tree (ca. 1 m diameter), ca. 7–8 m above the ground. The specimen was ca. 100 mm SVL. It had a grayish ground color with a pattern of darker transverse sinuous bands and a distinctive dark postorbital stripe. The hands and feet were distinctly webbed and a large fringe coming off the posterior margins of the hind limbs was visible. The caudal fringes were deeply crenulated. We consider this individual to be *P. kuhli* rather than *P. lionatum* based on its color pattern. The latter usually lacks distinct body bands and a dark postorbital stripe (Manthey and Grossman 1997).

At 1600 h along the same trail, but in lowland mixed dipterocarp forest at 200 m in elevation, we saw a single *L. bowringi* foraging on the forest floor. The specimen was ca. 40 mm SVL, had an elongate body and tail with relatively short limbs, and a shiny brownish body with a dark dorsolateral stripe bordered below by reddish coloration on the flanks.

COMMENTS ON OTHER SPECIES

Berry (1975) listed *Philautus vermiculatus* (Vermiculated Bush Frog) as occurring on Pulau Tioman. Lim and Lim (1999) speculate that Berry's listing may have stemmed from Hendrickson's (1966b) indecisive identification of an adult male from Pulau Tioman as *P. aurifasciatus* and that Berry (1975) may not have had access to specimens to confirm Hendrickson's (1966b) listing of this species. Therefore, Lim and Lim (1999) did not include *P. vermiculatus* as part of the island's herpetofauna. However, Berry (1975) also listed *P. aurifasciatus* from Pulau Tioman. Both are montane species and we (JAM and LLG) have observed them in sympatry at Bukit Larut in Perak, Peninsular Malaysia. Thus, the potential for both species to occur on the island exists. We list both species as present, with *P. vermiculatus* as unconfirmed because Berry (1975) cited no material, and *P. aurifasciatus* as confirmed based on Hendrickson's (1966b) specimen. Clearly, a series of *Philautus* needs to be collected from the montane regions of this island to resolve the issue.

Cnemaspis cf. *nigridia* (Dark Round-eyed Gecko) was first reported from Pulau Tioman as *Cnemaspis* sp. by Hendrickson (1966a), but was later referred to *C. nigridia* (Denzer and Manthey 1991; Manthey and Grossman 1997; Lim and Lim 1999). Hendrickson (1966a), however, noted that this population is distinguished from *C. nigridia* by "important differences in scalation" as well as in lacking femoral pores. This population is currently being described by Indraneil Das of the Institute of Biodiversity and Environmental Conservation, Universiti Malaysia, Sarawak and LLG as a new species. *Cnemaspis nigridia* occurs in Sarawak and the Natuna Islands but is not known from Peninsular Malaysia (Das and Bauer 1998).

Discussion

The new records reported here together with the recent works by Day (1990) and Lim and Lim (1999) indicate that the herpetofauna of Pulau Tioman almost certainly remains incompletely known. The steep, mountainous interior and rocky coastline of this island are relatively inaccessible and large tracts of forest remain unexplored. Thus, it is probable that a number of forest-dwelling species, especially small secretive taxa, remain to be discovered. Equally important is the fact that many of the reported species are known from only one or two specimens, and some of these, as well as others known from larger series, show morphological differences from their mainland counterparts (Day 1990; Hendrickson 1966a,b; Lim and Lim 1999). Thus, it is important that series of specimens of each species be obtained and that appropriate morphological and molecular comparisons be made to their Malayan and Bornean counterparts to assess the actual levels of diversity and endemism. As previously noted, potentially undescribed species include *Rana* sp. (Hendrickson 1966b), *Cnemaspis* sp. (Das and Grismer, *in prep.*), *Dibamus* cf. *alfredi*, *Oligodon signatus* (Day 1990), and *Trimeresurus popeiorum* (see Lim and Lim 1999). Known endemics include *Ansonia tiomanica* (Hendrickson 1966b) and *Cyrtodactylus tiomanensis* (Das and Jim 2000).

Acknowledgments.—For comments on the manuscript and identification we thank I. Das. This work was supported by the Presidential Grant from La Sierra University awarded to LLG.

Mark-recapture studies are often used to provide valuable life history information for animal populations. However, long-term marking of larval amphibians has been problematic because of their small size, delicate skin, and ability to regenerate tissues (Cecil and Just 1978; Donnelly et al. 1994; Seale and Boraas 1974). Procedures that have been used to mark larvae include fin-clipping (Turner 1960), whole-body staining with neutral red (Guttman and Creasey 1973; Herreid and Kinney 1966), injection of mineral oil and petroleum jelly mixtures (Seale and Boraas 1974), application of fluorescent pigments with gas pressure (Ireland 1989; Taylor and Deegan 1982) or heat brands (Ireland 1973), and application of a Congo red and dimethyl sulfoxide paste (Ireland 1989). However, these methods are cumbersome, inhibit growth (Travis 1981), do not produce unique marks, or are only useful for short-term studies. Passive integrated transponder (PIT) tags have been used to mark newts and spadefood toads (Fasola et al. 1993; Jehle and Hodl 1998) as well as metamorphic ambystomid salamanders (Ott and Scott 1999). However, these tags are too large for many larval amphibians. Toe-clipping has been the traditional method for marking amphibians (Ferner 1979), but some larvae may regenerate toes too quickly (<1 mo.) for use in long-term studies. In addition, larvae sometimes suffer toe injuries that make identification difficult (Ott and Scott 1999). As a result of these problems, field experiments that require the individual identification of amphibian larvae have been limited.

Subcutaneous injection of acrylic polymers is a method that has been successful for long-term marking of fish (Kelly 1967; Lotrich and Meredith 1974), adult salamanders (Ireland 1989; Wooley 1973), and tadpoles (Anholt et al. 1998; Cecil and Just 1978). These polymers are non-toxic and the marks can remain visible for a year or more. Each individual can also be given a unique mark by using several different colors and multiple mark locations. This method is efficient and cost-effective. However, it has yet to be tested on larval salamanders.

Larval salamanders are an important component of first order high-gradient streams because they are often the top predators in these fishless systems. The Blue Ridge two-lined salamander, *Eurycea wilderae* Dunn, is the most abundant larval salamander in the headwaters of the study region (Bruce 1985) and is the focus of our study. In these streams, hatchlings of *E. wilderae* appear in April or May, and the larval stage lasts one or two years (Bruce 1982, 1985, 1988; Voss 1993). The specific objectives of our study were to evaluate the polymer injection method in field trials and to use mark-recapture data to determine individual growth rates of larval *E. wilderae*.

This study was conducted in a first order stream that drains catchment 53 at the Coweeta Hydrologic Laboratory, Macon County, North Carolina. Vegetation consists of mixed hardwoods with a dense riparian understory of rhododendron (*Rhododendron maximum*). This stream was treated with the insecticide methoxychlor in 1980 to examine the role of invertebrates in processing organic matter (Cuffney et al. 1984; Wallace et al. 1982; Wallace et al. 1986). However, following treatment, the stream quickly recovered to reference conditions (Lugthart and Wallace 1992; Wallace et al. 1982; Wallace et al. 1997). Detailed descriptions of the Coweeta basin are provided by Swank and Crossley (1988). In addition to *E. wilderae*, four other salamander species are common in the headwaters at Coweeta: *Desmognathus quadramaculatus*, *D. monticola*, *D. ocoee*, and *Gyrinophilus porphyriticus*.

The entire wetted area of a 100-m reach was sampled for *E. wilderae* larvae approximately every month from November 1997 through June 1999. The stream was sampled at night with a head lamp and aquarium dip net (15.5 × 12 cm). Only loose cover objects (e.g., cobble, wood, leaves) were turned over when searching for larvae to minimize disturbance to the stream. Captured larvae were placed in individual 20 mL plastic vials filled with stream water. Vials were then placed on ice in a cooler.

In an on-site laboratory, each larva was anesthetized in Petri dishes containing 0.1% tricaine methylsulfonate (MS-222) (Beachy 1994). Snout-vent length (SVL) was measured to the posterior margin of the vent to the nearest 0.5 mm using a dissecting scope and vernier calipers. The anesthetized larvae were then placed on a damp paper towel under a dissecting scope. A Liquitex® acrylic polymer emulsion (available at most art supply stores) was injected into the tail using a 3 cc syringe with a 26 gauge 16 mm needle as described by Cecil and Just (1978). Initially, six different colors were used: blue, green, red, white, purple, and yellow. However, yellow was abandoned because it was difficult to see. Marks were inserted just under the skin of the tail immediately behind the hind legs. This insertion point left a mark that was visible if the tail was subsequently lost. Two discrete marks could be placed on either side of the tail, a feature that allowed the same color to be used twice on one side (Fig. 1). Marking newly hatched larvae (<14 mm SVL) was more difficult but still possible. After some practice, each larva could be measured and marked within five min. The five colors and four mark locations allowed for ca. 3,000 unique combinations. Following placement of a mark, larvae were revived in stream water, returned to their plastic vials, refrigerated overnight, and released at the point of capture the following morning or evening.

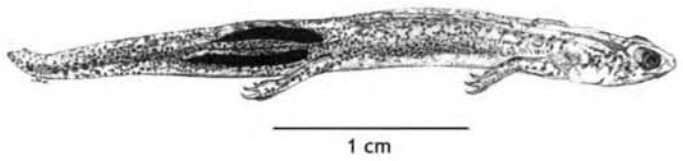

FIG. 1. A marked *Eurycea wilderae* larva demonstrating the location of color bands.

To determine growth, SVL was first converted to ash-free dry mass (AFDM) using a length-weight regression derived for *E. wilderae* in the study stream:

$$M = 0.0023L^{3.09} \quad (r^2 = 0.96, p<0.001, N = 22)$$

where M is larval mass (mg AFDM) and L is SVL (mm) (Lugthart 1991). Ash-free dry mass is a more accurate measure of growth than SVL or wet weight because it accounts for inorganic matter in guts. Individual daily growth rate (g) was then calculated as:

$$g = \ln(M_2/M_1)/t$$

where M_1 = initial larval mass, M_2 = final larval mass, and t = time interval in days (Romanovsky and Polishchuk 1982). Exponential growth was assumed. Average growth was also determined by plotting the mean biomass by sample date beginning after the hatchlings appeared in May 1998. In addition, we tested for differences in mean SVL of marked and unmarked larvae for each sample date throughout the study period using t-tests. We used a Mann-Whitney U-test when data failed to meet the assumption of normality.

To assess mark duration, 20 larvae were collected from an adjacent headwater stream and returned to the laboratory. These larvae were marked following the procedure described above and maintained in an aerated 37.9 L aquarium in a laboratory cold room at 5°C. Though this temperature is lower than the average annual temperature in the stream, these temperatures are encountered in winter and the larvae remain active. Moss-covered stones were collected from the stream and added to the aquarium for refuge. Water was changed weekly and larvae were fed freeze-dried *Daphnia* sp. However, *Daphnia* sp. consumption was not directly witnessed during laboratory study period. Larvae were checked regularly for any fading of marks or mortality. After one year, surviving larvae were returned to the stream where captured.

A total of 428 *E. wilderae* larvae were captured, marked, and released during this study. Ninety-eight individuals were recaptured and used for growth determination (~23% of the total marked). Of the 98 recaptured larvae, 32 were recaptured on more than one sample date. Though growth slowed slightly in the winter, growth was nearly linear over the year (Fig. 2). The average individual daily growth rate for *E. wilderae* larvae was 0.0024 d^{-1} (± 0.0002 S.E).

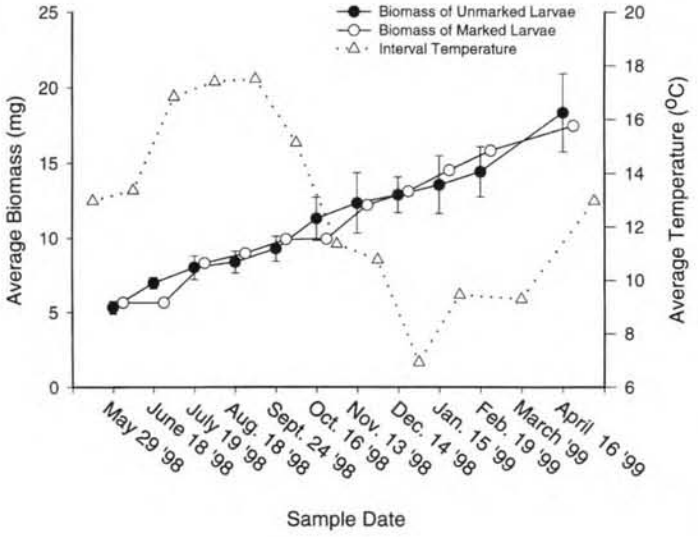

FIG. 2. Average biomass (mg) for all marked and unmarked (± 95% C.I.) *Eurycea wilderae* larvae by collection date beginning when hatchlings first appeared in spring. Stream temperature is plotted as the average between sample events.

Given their delicate appearance, the larvae were surprisingly durable during marking. They typically recovered from the anesthetic within ten minutes of returning to vials of stream water. A poorly placed mark resulted in the death of one larva, but all others were alive at the time of release with no apparent change in behavior from pre-marking. Larvae were recaptured up to eight months after marking (Fig. 3). The average biomass and SVL of marked larvae was not significantly different from unmarked larvae on all but one date ($p>0.05$)(Fig. 2) when recapture sample size was low ($N = 1$). This indicates that marking had little, if any, effect on growth. In the laboratory aquarium, all 20 marked larvae survived at least six months and 17 survived for a full year. Fading of marks was sometimes evident in both the field and laboratory but individual identification was always possible.

Amphibian larvae typically show reduced growth during winter (Beachy 1997), but our results show that *E. wilderae* growth was nearly linear throughout the year. Beachy (1997) found a similar linear growth pattern for larval *E. wilderae* in cage experiments. Our daily individual growth rate of 0.0024 d^{-1} agrees closely with a previous study that determined *E. wilderae* larval growth using chambers in a nearby headwater stream. In that study, the average individual growth rate from three different field trials was 0.003 d^{-1} (Lugthart 1991). However, results from chamber experiments must be interpreted with caution because larval densities and prey availability can influence growth rate (Petranka and Sih 1986; Scott 1990; Smith 1990).

By using acrylic marks, we were able to determine growth rates for individual, free-ranging larvae. Travis (1981) found that whole body staining with neutral red reduced growth of tadpoles and warned that any marking method might adversely affect growth. However, the acrylic polymers are non-toxic and there were no discernable differences in SVL or biomass between marked and unmarked larvae by sample date. There is therefore no evidence to indicate that marks affected growth.

The high survival rates of marked larvae both in the field (up to eight months after marking) and laboratory (up to one year) also indicated the marks had a negligible effect on survivorship. Our laboratory aquarium survival rate (85% after 1 yr) was much higher than those reported for *Eurycea* spp. in artificial streams over shorter time periods (27% over ~ 4 mos. in Resetarits 1991; 39% over ~2 mos. in Gustafson 1993; and 31% over ~3 mos. in Gustafson 1994). However, our higher survival rate could be partially attributed to reduced metabolic demand associated with lower laboratory temperature. The recapture time interval curve (Fig. 3) is indicative of the Type III survivorship curve (Deevey 1947) that has been previously documented for *E. wilderae* (Bruce 1988). The slope of this line may therefore be attributed to natural mortality or emigration rather than mark effects.

This study demonstrates the effectiveness of subcutaneous acrylic polymer injection for long-term monitoring of larval salamander populations. This method provides a practical and cost-efficient way to conduct field studies of the top predators in small, fishless streams. Because unique marks can be generated quickly, the method can easily be used not only to assess larval growth, but also population size and individual movements. Individual growth data can also be used to determine secondary production (Benke 1984; Waters 1977). Mark-recapture studies offer several additional advantages over cage experiments. For example, growth can be determined under natural conditions with realistic prey levels. In addition, natural movements can be measured and thus add to our understanding of species colonization and dispersal.

According to Ferner (1979) an ideal mark or tag should: 1) not affect individual survivorship or behavior, 2) uniquely identify individuals, 3) remain over the individual's lifetime, 4) be easily discernable, and 5) be easily applied in both field and laboratory studies. In addition, the marking or tagging method should be cost-effective and limit handling time of an individual (Ott and Scott 1999). Acrylic polymer injection meets most of these criteria and is currently the only viable method for *E. wilderae* larvae. A potential problem with this method is that the marks may increase larval visibility and thereby increase predation pressure from larger salamanders such as *D. quadramaculatus, D. monticola,* and *G. porphyriticus*.

Choice of an appropriate marking or tagging method should

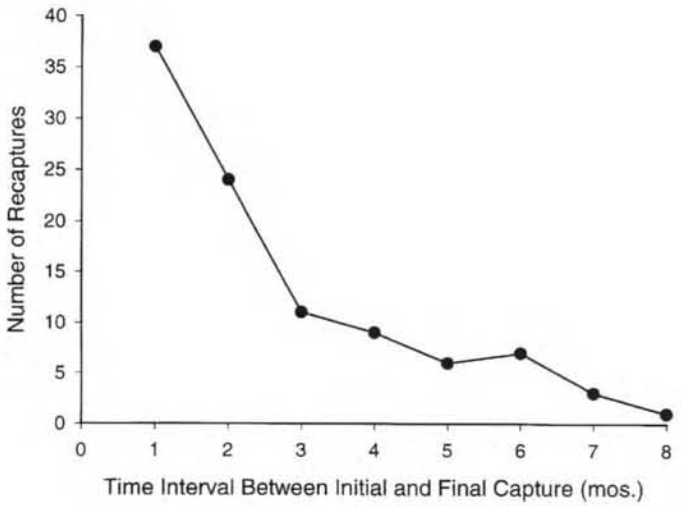

FIG. 3. Time interval between initial marking and final recapture for all *E. wilderae* collected from November 1997 to June 1999.

depend on the individual species, life history stage, and duration of the study period. Any one or a combination of polymer injection, PIT-tagging, and toe-clipping should be suitable for most amphibians. Polymer injection has proven an effective method for long-term marking of amphibian larvae and small-bodied adults, while PIT-tagging and toe-clipping remain effective in marking larger animals. The latter two methods have the added benefit of near invisible marks. In some cases, it may be desirable to use a combination of marking methods on the same individuals. For example, polymer injection could be used to mark individuals throughout the larval stage and, following metamorphosis, PIT-tags or toe-clips could replace the polymer marks. Such a long-term study design would provide valuable life history information and potentially aid amphibian conservation efforts.

Acknowledgments.— We thank Erica Chiao for her artwork and John Hutchens and Wyatt Cross for their comments on earlier versions of this paper. We also thank Sharyn Marks, Chris Beachy, and Don Ashton for providing valuable suggestions. This research was supported by National Science Foundation grant DEB-9629268.

Effective survey methods are needed for the marbled salamander (*Ambystoma opacum*) because of the species' rarity in the northeastern United States (DeGraaf and Rudis 1983) and increasing residential development that is affecting their upland habitats. Terrestrial surveys for adults are either impractical given the species' fossorial lifestyle (Petranka 1998) or costly (e.g., drift fences and pitfall traps; Dodd and Scott 1994). Larval surveys may be optimal because larvae can remain in pools for up to 7–9 months in some years (pers. observ.; Stewart 1956), creating a long window of opportunity for surveys. Aquatic funnel traps have been used successfully to capture other larval amphibians (Adams et al 1997; Bury and Major 1997; Fronzuto and Verrell 2000; Richter 1995; Wilson and Pearman 2000) and nocturnal visual surveys are a standardized transect surveying method commonly used in amphibian studies (Crump and Scott 1994; Thoms et al. 1997). We evaluate these two techniques for larval marbled salamanders. Specifically, we: (1) compare the results of each technique for determining presence and an index of relative abundance of marbled salamander larvae; (2) quantify the effect of time of year and survey intensity on the results of nocturnal visual surveys; and (3) describe the costs and logistical constraints associated with each technique.

We selected a sample of vernal pools in western and central Massachusetts using a hierarchical approach. We used the Massachusetts Natural Heritage Program's database to identify known marbled salamander sites within the study region. From this distribution, we selected five initial sampling areas that were well-distributed throughout the study region. Each initial sampling area consisted of a 3 km radius circular area roughly centered on one or more known marbled salamander sites. Within this 3 km circle, we mapped land cover and delineated all wetlands using aerial photographs (1991 color infrared, 1:40,000). We classified all temporary wetlands (e.g., vernal pools) as potential marbled salamander breeding habitat. Within each 3 km circle, we positioned a 1 km radius circle around the highest density cluster of potential breeding habitat, regardless of whether it contained any known marbled salamander sites. These five 1 km radius areas represented our final sampling areas.

We sampled a total of 97 pools distributed among the five sampling areas (Table 1) using both surveying techniques during the winter and spring of 1998. Each pool represented a separate observation (i.e., experimental unit) in the analyses described below. We sampled pools using bottle traps (Richter 1995) for 13 days between February 1 and March 1, when larvae were approximately 5 to 6 months old. The number of bottle traps placed in each pool was proportional to the surface area of the pool. We placed two traps per 10 m^2 (range 1–5 traps/pool), which represent a more intensive survey than recommended by Adams et al. (1997). Traps were randomly located within the pools at water depths between 0.5 and 0.75 m. If necessary, trap location and height were adjusted in response to fluctuations in water levels during the trapping period. Traps were baited with shrimp-scented salmon eggs and checked approximately every other day. Amphibian captures were recorded and released.

We conducted nocturnal visual surveys between March 1 and May 1. Each pool was sampled once during this period and all pools within a sampling area were surveyed on the same night. Each survey began shortly after dark and continued until all pools within the sampling area were surveyed. Pools were surveyed using transects; two observers walked parallel to one another, roughly 10 m apart, across the deepest section of the pool and then in opposite directions around the entire periphery of the pool approximately 2 m from the shore. Each observer utilized a high-powered flashlight to search and counted larvae within a 4 m wide swath.

After the 1998 season, we chose one of the five sampling areas to conduct more intensive tests evaluating the effect of timing and frequency of nocturnal visual surveys. During 1999, nocturnal

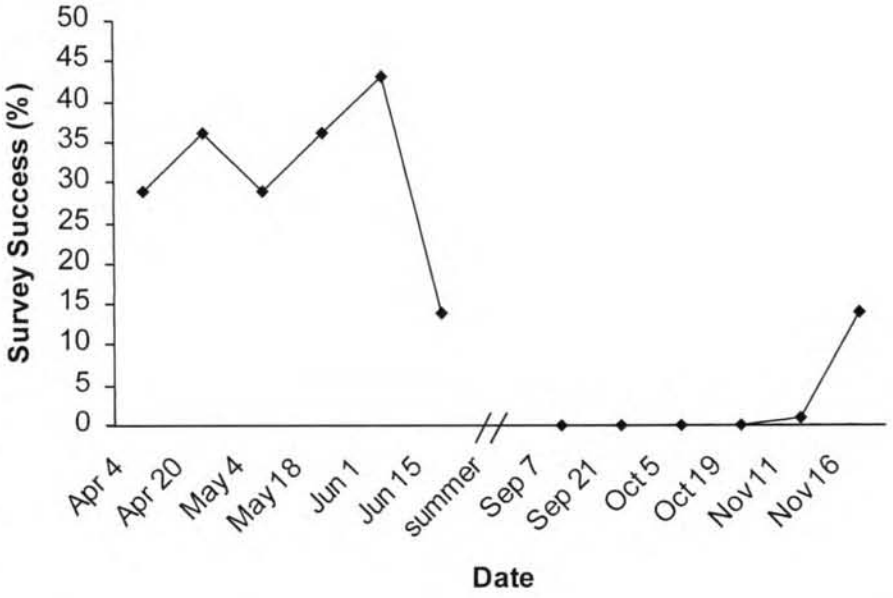

FIG. 1. Success (% occupied pools with detections) of nocturnal visual surveys at detecting marbled salamander larvae in relation to survey date in South Hadley, Massachusetts, during spring and fall sampling seasons, 1999. The break in the horizontal axis represents the summer period when pools were dry.

TABLE 1. Marbled salamander presence and total abundance in vernal pools distributed across 5 sites in Massachusetts during 1998 using two sampling techniques aquatic bottle traps and nocturnal visual surveys. The numbers in 'presence' columns represent the number of pools with marbled salamanders present at a given site. The numbers in 'abundance' columns represent the total abundance across pools at a given site.

		Presence		Abundance	
Site	No. Pools	Bottle Trap	Nocturnal Visual Survey	Bottle Trap	Nocturnal Visual Survey
Charlton	15	0	0	0	0
Holyoke	22	7	7	69	387
Leverett	24	0	2	0	116
South Hadley	19	6	6	22	448
Sutton	17	0	0	0	0
Totals	97	13	15	91	951

visual surveys (as described above) were conducted on a bi-weekly basis at 14 pools within the South Hadley sampling area, except during periods when the pools were iced over or dry.

We quantified the effectiveness of each survey technique at determining presence and an index of relative abundance of marbled salamander larvae. We conducted a Chi-square test of independence using all pools with and without marbled salamanders, testing the null hypothesis that there is independence between techniques in determining presence/absence. Also, we computed a Pearson's product-moment correlation in larval abundance for the two survey methods using pools with marbled salamanders, as determined by either technique, as independent observations. To compare efficacy of the survey techniques, we described the logistical constraints associated with each technique and compared the mortality rates between techniques.

To evaluate the effectiveness of nocturnal visual surveys in relation to the time of year and sampling intensity (i.e., number of surveys), we plotted survey success against time of year and sampling frequency for the 14 pools intensively sampled in the South Hadley sampling area. To construct the latter plot, a sampling intensity of one represented a single survey; success for a single survey was computed as the number of pools in which larvae were detected on that survey divided by the total number of pools with known marbled salamander populations. The mean survey success for a sampling intensity of one was computed as the average success rate for all the surveys (N = 12). A sampling intensity of two represented every possible combination of two consecutive surveys; success for each two consecutive surveys was computed as the number of pools in which larvae were detected by either survey divided by the total number of pools with known marbled salamander populations. The mean survey success for a sampling intensity of two was computed as the average success rate for all the 2-survey combinations (N = 11). This procedure was repeated for each sampling intensity between 1 and 12. Note that this procedure results in decreasing sample sizes as sampling intensity increases.

Nocturnal visual surveys were slightly more effective than bottle traps at determining the presence of marbled salamanders (Table 1), although the detection of presence was not independent between techniques ($\chi^2 = 82.08$; df = 1; $P = < 0.005$). Larvae were detected by both survey techniques at 13 of 97 (13.4%) pools. At an additional two pools (3% of total, 13% of pools with salamanders), larvae were detected by nocturnal visual surveys only. In addition, higher counts of marbled salamander larvae were recorded from nocturnal visual surveys (Table 1). Despite differences in absolute relative abundance, the results from these two survey methods were highly correlated after removing one outlier ($N = 14$; $R^2 = 68\%$; $P = 0.005$), indicating that both procedures can be used to derive a similar index of relative abundance. The outlier pool was excluded from analysis because thick vegetation throughout the pool prevented us from effectively conducting nocturnal visual surveys.

There were logistic constraints with both methods. Bottle traps caused higher direct mortality (5 adult *Ambystoma maculatum*, 2 adult *Rana sylvatica*, and 8 adult *Notopthalmus v. viridescens*) by exposing individuals to predation and freezing temperatures during cold nights. No mortality was observed with nocturnal visual surveys. Unobserved mortality may have been caused by walking through pools (both methods). Based on the number of days required to conduct each survey method, the effort required to bottle trap one pool was approximately three times greater than that required for visual surveys.

The effectiveness of nocturnal visual surveys varied with time of year. Spring surveys were more successful than autumn surveys (Fig. 1). The highest success occurred immediately prior to metamorphosis into terrestrial juveniles (June 1, Fig. 1), although previous studies found marbled salamanders at intermediate sizes to be more active then older larvae (Anderson and Graham 1967; Hassinger et al. 1970). There are a couple possible explanations for the relatively low effectiveness of autumn surveys. Immediately after hatching in the autumn, larvae have been observed spending proportionately more time in the pond bottom at night where they would be undetectable with nocturnal visual surveys (Anderson and Graham 1967; Hassinger et al. 1970). In addition, early autumn rains associated with Hurricane Floyd caused the pools to completely fill before all adults had migrated to the pools. Consequently, it is possible that reproductive success was partially or totally affected, leading to lower detection rates. Given that detection rates change with time, our earlier results comparing nocturnal visual surveys and bottle traps may be biased because of differences in the timing of surveys (bottle traps February–March, and nocturnal visual surveys March–May).

The effectiveness of nocturnal visual surveys also varied in relation to sampling intensity. Specifically, the success rate increased non-linearly with increasing sampling frequency (Fig. 2). Eight surveys were needed to detect salamanders in 91.6% of the pools where they were known to occur. These trends may reflect the fact that three pools had the presence of larvae detected during only one or two surveys. When these pools were removed the relation-

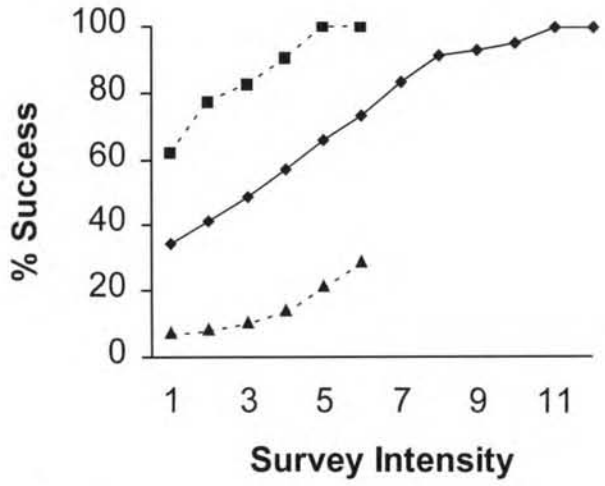

FIG. 2. Success (% occupied pools with detections) of nocturnal visual surveys at detecting marbled salamander larvae in relation to survey intensity (i.e., number of surveys; see text for details) in South Hadley, Massachusetts, during 1999. The diamonds represent the combined spring and fall surveys (N = 12); the squares and triangles represent the spring (N = 6) and fall (N = 6) surveys, respectively.

ship became more linear. Sampling intensity required to achieve the same level of success was much lower in spring than autumn (Fig. 2).

Given the increasing impacts of anthropogenic disturbance (e.g., urban development) on marbled salamander breeding habitat, there is growing interest in methods to identify and protect critical habitat. Determining marbled salamander presence is prerequisite to developing a better understanding of the species' habitat needs and in providing justification for protecting vernal pools from human impacts. Our findings suggest that nocturnal visual surveys were the least intrusive and expensive, and are slightly more accurate at detecting presence. Both methods provide an index of relative abundance, although nocturnal visual surveys may give counts that are closer to the true population abundance. We also show that the timing and intensity of surveys are important considerations; multiple site visits in late spring may be optimal.

Acknowledgments.—We thank Al Richmond, Scott Jackson, Scott Melvin, Richard DeGraaf, and Bob Brooks for their technical advice. Janice Stone assisted with the interpretation of aerial photography and wetlands mapping. We also thank Mark Grgurovic, Dan Wong, Miranda Buck, Suzie Fowle, Silvia Schmidt, and Leeanne Siart for help in the field. Funding for the project was provided by the Millennium Power Plant Project, and negotiations were handled by the Massachusetts Division of Fisheries and Wildlife.

Coverboards have been a standard sampling tool for herpetologists for over a decade. Although wooden or tin coverboards are useful in augmenting time-constrained sampling (Grant et al. 1992), they also can be cumbersome and awkward to carry to sampling sites, thus restricting their use in field sites that are not easily road-accessible. An alternative material that has proven effective and cost-efficient is heavy-grade rolled roofing material. Confirmation that this material is environmentally safe for sampling could ease concerns regarding its use for capturing reptiles and amphibians.

Roofing material is a less costly and more convenient alternative to wood or tin coverboards (Table 1). Weighing approximately 2.7 kg per 90 cm^2 sheet, roofing coverboards are considerably lighter and easier to transport than particle board, which weighs 7.1 kg per coverboard, and are approximately equal in weight to plywood. Although tin is lighter, weighing 1.8 kg per coverboard, it, like wood, is difficult to carry because of its rigidity. One roll of roofing material weighs 34.7 kg and yields twelve 90 cm^2 pieces. Depending on a person's strength, a whole or half roll can be hoisted over a shoulder, carried into the field, and cut into sections on site using a carpet knife.

Roofing coverboards also seem to be comparable to wood and tin in sampling effectiveness. Fourteen roofing coverboards were monitored at Ellenton Bay and Bulldog Bay on the Savannah River Site (SRS, Gibbons and Semlitsch 1991), near Aiken, South Carolina for approximately two weeks in May 1999 and June 1999, respectively. Positioned at the water's edge, they yielded encounters with individuals of nine species, including snakes (*Farancia abacura, F. erytrogramma, Agkistrodon piscivorus, Nerodia fasciata*), frogs (*Acris gryllus, Rana utricularia, Gastrophryne carolinensis*), salamanders (*Ambystoma talpoideum*, primarily metamorphs), and hatchling turtles (*Kinosternon subrubrum*).

However, because roofing material is synthesized from petroleum products, the environmental safety of its use in wetland areas may be a source of concern. An oily sheen was often present on the water's surface in wetlands on the SRS where roofing coverboards were in use for herpetological monitoring studies. Therefore, whether roofing decomposes in the field and leaches harmful petroleum substances into surrounding waters needs to be addressed to ensure that the method is not detrimental to the environment and organisms being studied.

Certain concentrations of petroleum can be detrimental to amphibian development. Mahaney (1994) evaluated hatching rate, larval growth, and success of metamorphosis of *Hyla cinerea* exposed to used crankcase oil. Low level (10 mg/L, 55 mg/L) exposure to used crankcase oil had no effect on these parameters, but tadpoles raised in higher concentrations (100 mg/L; equivalent to levels produced by runoff from service stations) had a significantly reduced growth rate and never proceeded to metamorphosis. Lefcort et al. (1997) compared the effects of motor oil and silt on fitness parameters in the salamander *Ambystoma t. tigrinum*. They found that larvae raised in large outdoor tubs with concentrations of 7.6 ml oil/L water exhibited significantly lower body size, weight, length, and head width. In their laboratory studies, however, where larvae were fed fresh algae, there was no developmental variation between larvae reared in oil-contaminated and control tubs. This difference was attributed to the diminished levels of algal growth in the contaminated outdoor tubs, which reduced food availability.

The toxicity of some petroleum products to wildlife has been shown to intensify with exposure to sunlight. Oris and Giesy (1985, 1987) found that 6 of 12 polycyclic aromatic hydrocarbons (PAHs) were found to be acutely toxic to fathead minnows only when they were exposed to sunlight. Other studies have also shown that sunlight can magnify the toxicity of petroleum products. For example, Boese et al. (1997) recently demonstrated the photoinduced toxicity of fluoranthene to benthic crustaceans. And in an earlier study, Oris and Giesy (1985) found that anthracene, a linear 3-ring PAH formerly thought to be nontoxic to aquatic organisms, is acutely toxic to juvenile sunfish when exposed to sunlight.

Our study focuses on whether roofing material leaches detectable levels of petroleum products (particularly PAHs) in water when exposed to sunlight and May/June temperatures typical of South Carolina (mean minimum ~16°C, mean maximum ~31°C). Iridescent surface films (microlayers) were skimmed from the surface of wetlands where roofing was in use and analyzed to determine the presence of contaminant hydrocarbons. We previously sampled the surface microlayer in riparian pools located in Upper Three Runs Creek and in the Steel Creek Delta at the SRS.

Roofing material, water leachates, and surface films were analyzed by using a modification of the EPA Method 8100 (USEPA 1998). Solvent extracts of the various samples (described below) were reduced in volume to 1 ml using rotary, vacuum evaporation. Silica gel liquid chromatography separated the aliphatic fraction (f1) containing *n*-alkanes from the polyaromatic (f2) fraction. Hydrocarbon analyses of both the f1 and f2

TABLE 1. Weights and costs of various coverboard materials. Costs are derived from prices at Lowe's Home Improvement Warehouse, Athens, Georgia (May 1999). Different coverboard materials are sold in different bulk quantities.

Coverboard type	Dimensions (cm)	Weight (kg)	Cost (US $)/Coverboard
Roofing materials	90 x 90	2.7	$0.99
Particle board	61 x 122 x 1.6	7.1	$1.23
Plywood	61 x 122 x 1.0	2.2	$1.23
Tin	66 x 122	1.6	$1.93

fractions were performed on a Hewlett Packard (Atlanta, Georgia) 5890 Series II gas chromatograph equipped with a flame ionization detector (GC-FID), splitless injection, electronic pressure control (EPC), and autoinjector. Separations were achieved using a 30 m DB-5 (0.25 mm I.D., 0.25 µm film thickness) capillary chromatographic column (J&W Scientific, Folsom, California). Diesel range organics and PAH standards were used as retention time markers for compound identification.

Roofing material used for this study was Globe® Mineral Surfaced Roofing, which is coated on one side with white asphalt pebbles. Hydrocarbon analysis of the unweathered roofing material was completed by extraction and sonication (Tekmar®) of three replicates of a 5-gram sample in 100 ml of methylene chloride:acetone.

The first leaching experiment was conducted in borosilicate Erlenmeyer flasks (UV cutoff 290 mm, Zepp 1982) containing 100 ml of Milli-Q water. Three flasks containing 4–5 cm^2 (6–7 g) of submerged roofing were set in the sun for one week. Following the leaching period, the solutions were filtered through a funnel with glass wool (solvent rinsed) to remove any particulate material and the filtrates extracted three times with methylene chloride in a separatory funnel. The solvent extracts were combined and reduced in volume using rotary-evaporation, then analyzed for aliphatic and polyaromatic hydrocarbons. A second leaching experiment was conducted in Rubbermaid bins aligned along the edge of a Carolina bay (A Bay) at the SRS. Each bin contained 15 L of bay water (15 cm depth) and contained 30 cm x 45 cm of submerged roofing material. Sample and control bins (two each) were sampled after 28 days and analyzed as described above.

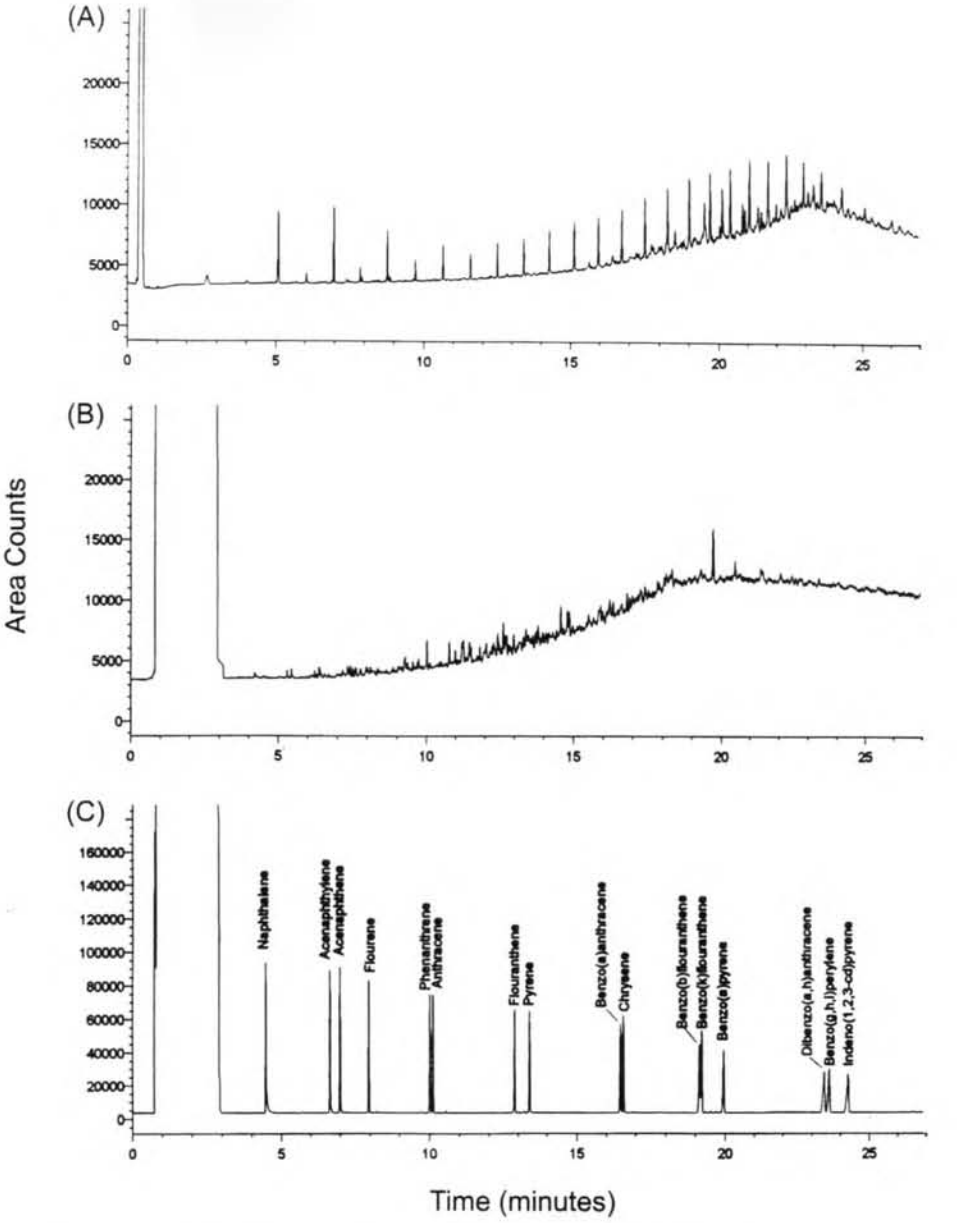

FIG. 1. Gas chromatograms with flame ionization detection of the aliphatic (A) and aromatic (B) hydrocarbon fractions isolated from roofing material, and a PAH standard (C). The x-axis represents increasing time.

To assess whether the iridescent sheens observed in the field were associated with nearby roofing or were a result of natural factors, microlayer sheens were collected from the water's surface in a Carolina bay where roofing coverboards had been adjacent to or partially submerged in water for three months. Microlayers were collected in solvent-cleaned glass jars and analyzed as previously described for the leachate experiment.

The roofing material was composed primarily of high molecular weight aliphatic hydrocarbons ranging from C_{22} to C_{40} (Fig. 1a). Much of the material was part of the chromatographically unresolved complex mixture of components characteristic of petroleum products. A small amount of material was observed in the aromatic fraction of the extract, mostly composed of unresolved components (Fig. 1b). Resolved aromatic components were present in concentrations <0.10 µg L^{-1} and none of these components had retention times corresponding with the EPA priority pollutant PAHs (Fig. 1c).

Although the three flasks containing submerged roofing contained aliphatic hydrocarbons, none contained detectable levels (>0.10 µg L^{-1}) of any of the 18 EPA priority pollutant PAHs. Likewise, the water samples taken from the bin exposures after the 28-day soaking period showed no evidence of PAH contamination.

In common field use, these coverboards are not wholly submerged; rather, they are placed at the water's edge or partially overlapping into the water. In such a setting, contact with soil microbes may play a role in further decomposition, but it seems unlikely that roofing would contribute PAHs to the surrounding environment. Chemical analysis of the iridescent microlayers from

wetlands where roofing had been in use showed that they did not contain any petroleum products.

Surface sheens are common in many wetlands where high inputs of detrital carbon generate surface-active compounds that accumulate as a thin film at the air-water interface. Humic substances, lipids, and proteins originating from higher plants and microorganisms have been shown to be components of the film (Mills et al. 1996).

In conclusion, roofing material has several logistical advantages for use in field studies in which coverboards are suitable. The finding that no chemical hazard is created for the animals that use roofing material for shelter or that are present in surrounding waters adds value to its use as a monitoring technique in some situations.

Amphibians, despite their vulnerable appearance, possess a veritable armamentarium of integumental defenses against both vertebrate and invertebrate predators. Chief among these are skin secretions, the major components of which have long intrigued biologists, chemists, and pharmacists alike. Researchers have employed a variety of methods to harvest skin secretions, some more invasive than others. Among the more invasive techniques are the injection of neurotransmitters (Barthalmus 1994; Bols et al. 1986) and whole skin extraction (Daly 1998; Das et al. 2000; Morikawa et al. 1992; Roseghini et al. 1976; Roseghini et al. 1986; Roseghini et al. 1988; Zasloff 1987). Whole-skin extraction (the removal and maceration of an entire amphibian skin) has two major disadvantages: introduction of contaminants to the sample and fatal outcome for the amphibian. Contaminants introduced by macerating whole skins can complicate sample cleanup, while the current worldwide decline in amphibian populations demands that they be treated as non-renewable resources. Fortunately, amphibian skin has an anatomy that permits simple harvest of its secretory products without injury to the animal itself.

Amphibian skin contains both mucous and granular glands (Pough et al. 2001). Granular glands produce the defensive compounds of interest. Each granular gland is encircled by a muscle responsive to electrical stimuli. Such stimulation results in ejection of the glandular contents onto the skin's surface, where they are readily collected. Researchers have used this technique to advantage and claim to have obtained results comparable to those of the whole-skin technique (Tyler et al. 1992).

Although others have used this electro-stimulation technique, they have relied upon commercially available but expensive devices (Tyler et al. 1992), or have not specified what equipment was used (Barteczko and Kuziemski 1970; Dockray and Hopkins 1975; Flucher et al. 1986; Lábler et al. 1968). We present here for the first time instructions for the assembly of a Transcutaneous Amphibian Stimulator (TAS), an affordable alternative to commercially available acupuncture units. It is a small handheld unit that is easily adapted for an individual researcher's needs in the field or in the laboratory. Powered by two 9-volt batteries, the TAS is an excellent device for collecting amphibian epidermal granular gland products without causing harm to the amphibian.

The TAS stimulation parameters were based upon those of the modified acupuncture unit used by Tyler et al. (1992). Pulsewidth of the stimulus is set at 2.5 or 5 msec, with a single-pole/double-

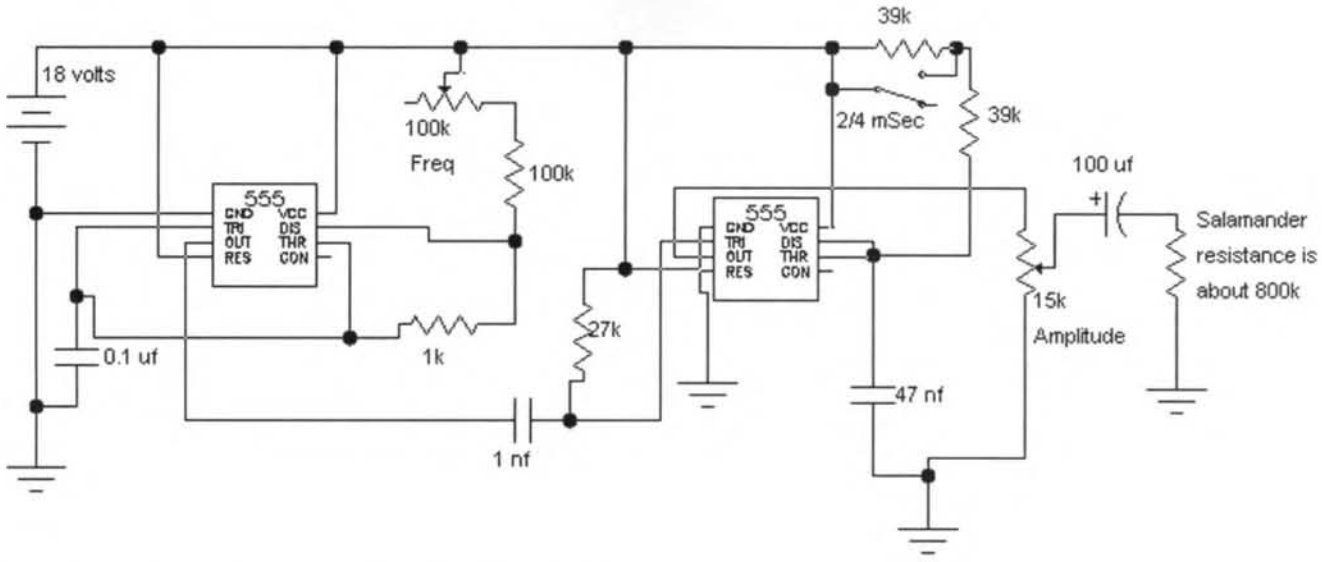

FIG. 1. Circuit diagram for the Transcutaneous Amphibian Stimulator (TAS).

throw switch, in conjunction with an ICM7555 timer in the monostable operation mode. A 15 kOhm potentiometer permits adjustment of the voltage from 0 to 18 volts. Frequency is adjusted within the range of 60 to 130 Hertz by use of a 100 kOhm potentiometer combined with an ICM7555 timer in the astable operation mode. The stimulus is harmlessly delivered by silver-silver chloride disk-electrodes (4.0 mm or 8.0 mm diameter; Warner Instrument Corporation, Hamden, Connecticut, USA). This type of electrode is ideal because of its lack of toxicity and non-abrasive surface. A less expensive alternative is the bare silver wire electrode, but it entails the risk, if of too narrow gauge, of perforating the amphibian's skin. Standard binding posts connect either type of electrode to the circuit. The TAS circuit can be built for approximately US $100 with commercially available parts (Mouser Electronics, Inc., Ottawa, Canada) by following the circuit diagram provided (Fig. 1). We housed our completed circuit in an 80 mm x 160 mm x 60 mm ROLEC watertight polycarbonate transparent Techno Case (Hammond Manufacturing, available through Mouser Electronics, Inc., Ottawa, Canada). Watertight cases with rubber O-ring-sealed fittings are recommended for fieldwork, but cheaper, non-watertight cases may be substituted for laboratory purposes.

Extraction of skin secretions is accomplished by first lightly moistening the animal with deionized water then gently massaging its skin with the activated TAS electrodes for 10–20 seconds (Fig. 2A). For our research we adapted the technique for the animals at hand, massaging anurans (with the exception of *Bufo americanus*) laterally and dorsally from neck to thigh; *Bufo americanus* directly on parotoid glands (Fig. 2B, showing production of the milky white secretion); and urodeles along base of tail. Coincident with stimulation, the animal is rinsed with deionized water. The aqueous solution is collected in a vessel held beneath the animal. Preparation of the secretion at this point varies with the intended purpose of the extraction.

The technique has any number of applications: the determination of evolutionary trends within different populations of a single species (Steinborner et al. 1996a; Steinborner et al. 1996b), differentiation of morphologically indistinguishable species (Daly 1998), in biochemical taxonomy (Cei et al. 1967; Cei et al. 1968 ; Cei et al. 1972), in pharmacology (Roseghini et al. 1986), in medi-

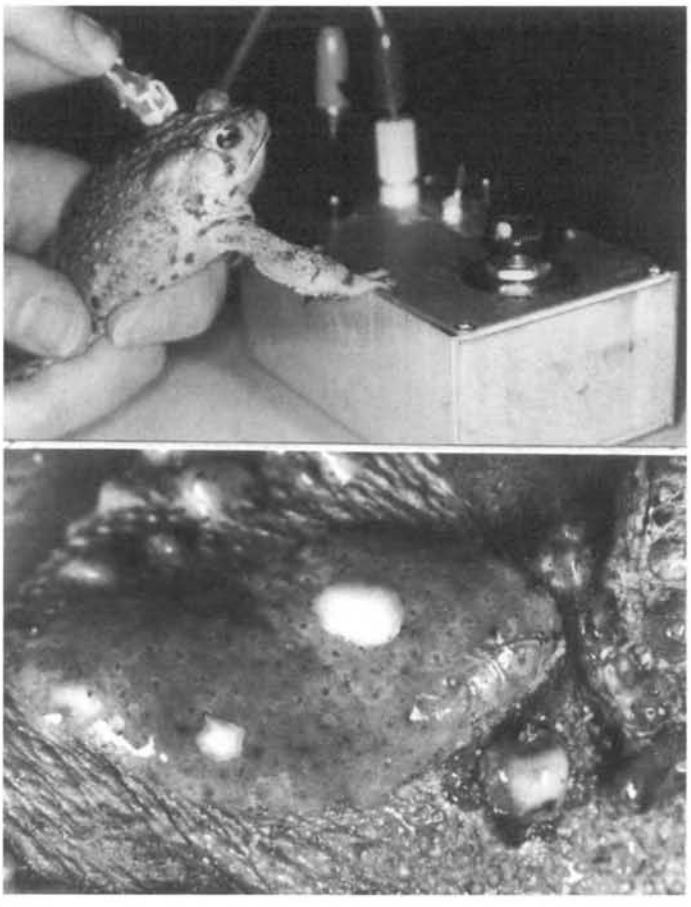

FIG. 2. A. The Transcutaneous Amphibian Stimulator (TAS) and a study subject (*Bufo americanus*). B. TAS-elicited defensive secretion (milky-white spots) from the parotoid gland of *B. americanus*. Photos by Tom Eisner.

cine (Barteczko and Kuziemski 1970; Bradford et al. 1996; Zasloff 1987), in chemistry and chemical ecology (Clarke 1997; Daly et al. 1987), and in behavioral studies including pheromonal (Wabnitz et al. 2000) and predator-prey interactions (Barthalmus and Zielinski 1988; Barthalmus 1994, Brodie 1983; Brodie and Gibson 1969). The TAS has also been used in our lab to study the production and chemical composition of amphibian-produced volatile compounds (unpublished data).

In our current studies of amphibian chemical ecology, we have used the TAS to collect secretions from the following species: *Ambystoma maculatum, A. tigrinum, A. jeffersonianum* complex, *B. americanus, Hyla chrysoscelis, H. gratiosa, Osteopilus septentrionalis, Plethodon cinereus, P. glutinosus, Rana catesbeiana, R. clamitans clamitans, R. c. melanota, R. pipiens, R. palustris, R. septentrionalis, R. sylvatica,* and *Scaphiopus holbrookii*. We have found that smaller amphibians require <10 V, <75 Hz, and 2.5 msec pulsewidths for induction of glandular emission, while larger animals require >10 V, >60 Hz, and 5 msec pulsewidths. No species required the use of >15 V to elicit granular gland discharge. Despite their size, ambystomatids require minimal settings (<10 V, 60 Hz, 2.5 msec) to elicit appropriate granular gland response. Among the species under study in this lab, secretory yields ranged from 10 to 100 mg per animal with the exception of the ambystomatids, which produced copious amounts (in excess of 200 mg per animal).

In conclusion, the TAS is a portable and inexpensive device for "milking" amphibians of their skin secretions. By being minimally harmful to the test organism, it is a distinct improvement over alternative techniques relying on whole-skin analysis or injection of epinephrine or acetylcholine. It is an ideal technique in chemical studies because the samples collected are relatively free of impurities and therefore in a condition requiring minimal preparation (filtration) prior to chromatographic and spectral analysis.

Acknowledgments.– We thank Tom Eisner for helpful suggestions and support on many levels, the Kieckhefer Adirondack Fellowship for previous and continuing grants in aid of this work, and Cranberry Lake Biological Station and Huntington Wildlife Research Forest for allowing J.B.G. to refine the TAS with use of their amphibians. We also thank Matthew Weeg for useful commentary and his great help in refining the electrode design, R. Wallace Clark for helpful comments on the manuscript, and Maria Eisner for photographic developing work. This work was supported in part by NIH grant #AI02908. All animal work was approved by the Animal Care and Use Committee of Cornell University under protocol #00-22 and some amphibians were collected in New York State under New York State Fish and Wildlife License #LCP01-199.

Minimizing Fungal Invasion During the Artificial Incubation of Sea Turtle Eggs

ANDREA D. PHILLOTT
School of Biological and Environmental Sciences
Central Queensland University, Rockhampton QLD 4702, Australia
e-mail: phillota@cqu.edu.au

The artificial incubation of sea turtle eggs has become increasingly common for research purposes. It usually involves the collection of eggs, transport to a laboratory (potentially long distance), then incubation within a container and/or incubator on sand or an artificial substrate such as vermiculite. During incubation it may be necessary to inspect eggs to monitor development and mortality, and maintain moisture conditions.

At all stages during these procedures, eggs are exposed to infectants which have the potential to kill a proportion, or all, of the eggs. To minimize egg mortality, precautions can be taken to reduce egg exposure to microbiota.

Collection.—Collecting eggs directly from the ovipositor minimizes their exposure to fungal spores dispersed during the turtle's body-pitting and egg-chambering. Eggs may be caught by a gloved hand placed in the rear of the egg chamber (part of the chamber may need to be widened). Though some species are more tolerant than others, care must be taken not to disturb the turtle by use of excessive light, or by touching the ovipositor and hind flippers. If eggs cannot be collected during oviposition, they may be excavated after laying has concluded, but this method increases contact with soil microbiota. Some workers have attempted to place a collection bag in the egg chamber during oviposition. This often disturbs the turtle, resulting in nest abandonment, collapse of the egg chamber during bag insertion, and difficulty removing it when full. This method may be more successful with species that do not dig a deep body pit and/or on beaches with relatively moist sand, where the rear of the chamber may be excavated completely for easier insertion and retrieval.

Eggs should be placed directly into sterile bags; autoclave disposal bags (e.g., Sarstedt®) are recommended because of their strength. Placing the bag inside a bucket helps support the weight of the eggs and prevents weakening and tearing of the bag under stress. The neck of the bag should be twisted and folded over before securing. Prior to transport or incubation, eggs can be washed in sterile distilled water or a solution such as Aricide® (Hibberd 1996) to remove microbes from the egg exterior. However, washing removes the cloacal mucous and its potential anti-fungal properties (Phillott, unpubl.). After washing, the exterior of the egg should be patted dry using a clean disposable cloth to remove excess water and prevent ice-crystal formation and disruption of the shell structure during low-temperature transport.

Transport.—Eggs may be transported long distances by following the procedures of Harry and Limpus (1989). Eggs depressed to 7–10°C (within 2 h of oviposition) may be held for 48 h, allowing collection of multiple clutches over several nights and subsequent transport. It is recommended that eggs remain in the collection bags during this time to minimize exposure to microbes. The bags should be arranged so that they are stable, and air spaces filled with clean, expanded polystyrene pellets for support and insulation.

Handling.—To minimize movement induced mortality, egg orientation should be maintained (Limpus et al. 1979; Parmenter 1980). Single-use sterile gloves should be worn, and eggs handled in a room or area with minimal air flow or disturbance. If the area is to be used permanently for incubation purposes, a dual door system with an intermediate isolation area minimizes air disturbance during entry and exit. Workers must wait in the isolation area until the first door has completely closed before opening the second.

Incubation.—Prior to egg collection, incubators should be cleaned with a 5% sodium hypochlorite bleach solution, then rinsed with a 5% solution of disinfectant. Incubation containers (which will hold the eggs) may be sterilized by autoclaving at 121°C for 15 mins with the mouth covered in aluminium foil, or with a 5% bleach solution followed by a sterile water rinse.

If incubating on sand, it should be collected from areas relatively free of organic material. Sand can be sterilized by autoclaving in small lots. Thermal sentinels (e.g., Thermalog® S strips) should be used to ensure effective heat sterilization at the core. These checks can be ceased when the performance of particular autoclaves, sand types, etc., is quantified.

Labels on cardboard or other biodegradable material should not be placed in or on the substrate during incubation as they provide nutrient sources for mycobiota. Instead, the exterior of the container should be labeled. The required moisture conditions are maintained by adding sterile water either from clean spray bottles, or by use of a sterile water, sub-surface trickle irrigator (as described by Phillott and Parmenter 2001). If the plastic tubing from the latter is to be re-used, it should be first be cleaned with a commercial algaecide (used in cleaning swimming pools) then rinsed with sterile water.

When removing eggs (to weigh, measure, candle, etc.) wear sterile, single-use gloves and ensure the equipment is clean and that air flow around the area is minimal. If eggs are to be weighed, sand can be removed using a soft brush that will not damage the eggshell. Using a cloth to remove sand has the potential to drag sand across the egg surface, disrupting structural integrity of the eggshell. Eggs that fail to develop a white spot, that show signs of yellowing, or have fungal growth on the exterior should be re-

moved. Mass egg mortality often follows fungal contamination of a single moribund egg as hyphae spread to adjacent viable eggs (Phillott and Parmenter 2001). This potential spread can be minimized by ensuring eggs are not in contact with each other, though this is not always practical.

In the event of egg invasion, species of fungi can often suggest the source of the contamination. *Fusarium oxysporum*, *F. solani* and *Pseudallescheria boydii* have been regularly isolated as soil-borne pathogens on the exterior of failed eggs (Phillott et al. 2001). In contrast, *Aspergillus* spp. have been contracted by air-borne contamination (unpubl.). Identification of the fungi may lead to its point of source, allowing protocols to be modified so as to eliminate contamination.

Acknowledgments.—Sincere thanks to: C. J. Parmenter and C. J. Limpus for advice on handling and transport of eggs; Central Queensland and Queensland Turtle Research volunteers who assisted in egg collection, handling, and transport; and C. Elder for advice on maintenance of incubators.

Captive Reproduction and Growth of the Broad-Striped Dwarf Siren (*Pseudobranchus s. striatus*)

CHARLES SCOTT PFAFF
and
KATHY BELL VAUSE
Riverbanks Zoo and Botanical Garden, PO Box 1060
Columbia, South Carolina 29202, USA
e-mail (CSP): spfaff@riverbanks.org

Dwarf sirens (*Pseudobranchus*) are aquatic salamanders endemic to the southeastern United States. There are two extant species, the southern dwarf siren (*P. axanthus*) and the northern dwarf siren (*P. striatus*). The northern dwarf siren consists of three subspecies (*P. s. striatus*, *P. s. lustricolus* and *P. s. sphenisus*) one of which, the broad-striped dwarf siren (*P. s. striatus*), is indigenous to South Carolina (Moler and Kezer 1993; Petranka 1998). The broad-striped dwarf siren inhabits cypress swamps and ponds in acid pine flatwoods, flooded ditches, marshes and other permanent and semi-permanent aquatic habitats from southeastern South Carolina to northern Florida (Conant and Collins 1991; Moler and Kezer 1993; Petranka 1998). Habitat loss and fragmentation as a result of development, agriculture, and silvaculture may be responsible for a decline of this salamander in South Carolina (S. Bennett, pers. comm.) Because of this, the South Carolina Department of Natural Resources has listed *P. striatus* as a state threatened species.

Most of the published life history data for *Pseudobranchus* species concerns *P. axanthus*. Although the life history of *P. striatus* may be similar to that of *P. axanthus*, for both species there is a general lack of data for growth rates, size and age at first reproduction, and many aspects of the juvenile and adult stages (Petranka 1998). According to Petranka (1998) there is "an almost complete lack of information on the natural history of *P. striatus*."

In 1994, Riverbanks Zoo and Garden attempted to establish a self-sustaining captive population of *P. striatus*. In July 1994, 0.0.6 *P. striatus* were collected in Hampton County, South Carolina and donated to RZG by the South Carolina Department of Natural Resources. Although the age of the specimens at the time of collection is unknown, it was latter determined that their small size corresponded with that of captive born young-of-the-year.

Husbandry.—The salamanders were initially housed in various glass and plastic aquaria ranging in size from 31 x 18 x 21 cm (LxWxH) to 50.8 x 25.4 x 34.2 cm. De-chlorinated tap water with a pH of ~ 7.0 was added to a depth of ~15.0 cm. Water temperatures were maintained between 23°C and 27°C. There was no mechanical, chemical, or biological filtration on any of the aquaria; however, 50% water changes were made weekly. Aquatic plants including duck weed (*Lemna* sp.) and bladderwort (*Urticularia* sp.) were added to all of the aquaria. A layer of substrate 2–4 cm deep consisting of small gravel, sphagnum moss, or leaf litter was added to some aquaria while others contained no substrate. Artificial lighting consisting of a 15-watt full spectrum fluorescent bulb and a 40-watt incandescent bulb was used on a single aquarium while the others had no supplementary lighting.

A variety of commercial, dry, flake fish food and live food was offered to the sirens ad lib. 3x/week. The preferred food item proved to be live blackworms (*Lumbriculus variegatus*) which were later fed exclusively. Live tubifex worms (*Tubifex* sp.) were not accepted as a food item.

The six wild-caught sirens readily acclimated to a captive environment and grew rapidly (Fig. 1). As far as could be determined, no one particular aquarium set-up proved to be more advantageous than another in terms of survival or growth rate.

Reproduction.—In May 1995, all individuals were assumed to be near adult size and an attempt was made to stimulate reproduction. *Pseudobranchus* are not considered sexually dimorphic. However, Petranka (1998) reports that "female *P. striatus* are on average slightly larger than males." Netting and Goin (1942) reported that in *P. axanthus*, the average total length (TL) of the five longest females they collected was 28% greater than that of the five longest males. The two longest animals at RZG (RZ 1260 and 1265), presumed to be females, and the two shortest (RZ 1261 and 1263), presumed to be males, were placed together in a 50.8 x 25.4 x 34.2 cm glass aquarium. Ambient water temperatures were

maintained between 25° and 27°C. The aquarium was located in a room with a glass skylight that provided natural photoperiods. Because *Pseudobranchus* are known to attach single eggs to underwater vegetation (Goin 1947; Netting and Goin 1942) live aquatic plants (*Utricularia* sp.) and plastic aquarium plants were maintained in the water column at all times. During the summer and fall of 1995, no breeding or courtship behavior were observed, nor did we observe any eggs. Noble (1930) reported that captive *Pseudobranchus* will eat the eggs of conspecifics so it is possible that eggs were laid but consumed.

In late October 1995, an attempt was made to ascertain if seasonal thermal and photoperiod cycling would stimulate reproduction. The group was moved into a hibernaculum where the air and water temperature was gradually lowered to 12°C and the photoperiod was reduced to 8/16 (L/D) h per day. Individuals were maintained under these conditions until early March 1996 when the temperatures were gradually raised to 27°C and the photoperiod increased to 14/10 (L/D) h per day. During the remainder of 1996, no reproduction or attempts at reproduction were observed. The same seasonal thermal/photoperiod cycle was again duplicated between October 1996 and March 1997. As in the previous year, no evidence of courtship or reproduction were observed during 1997.

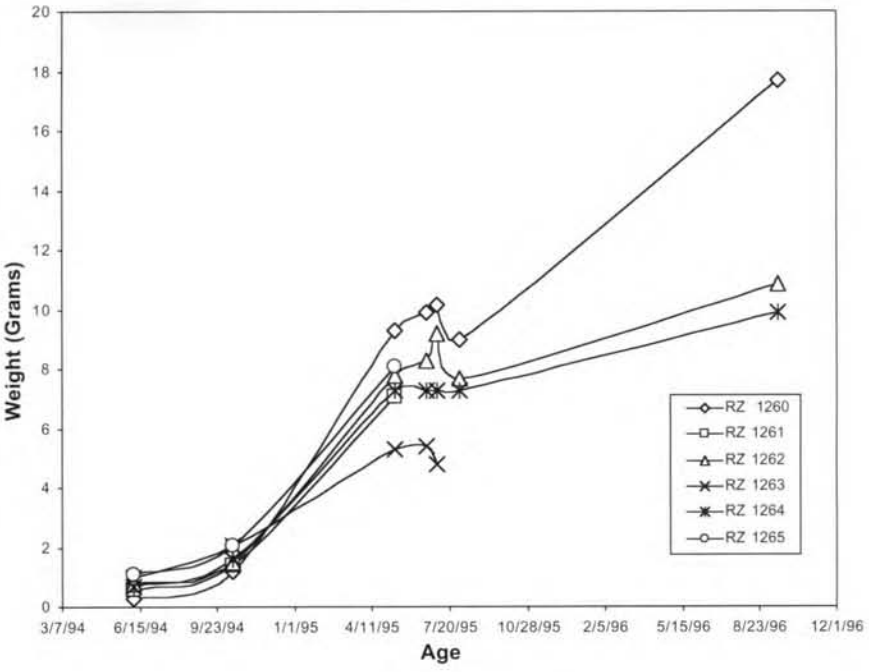

FIG. 1. Growth rates of six *Pseudobranchus s. striatus* collected as juveniles.

Beginning in October of 1998, the same group of four adult sirens was placed in a 107 x 74 x 30 cm plastic stock tank and moved outdoors. Unfiltered, untreated water from the lower Saluda River, which supplies the zoo's river water system, was added to the tank and fluctuated between 15 and 20 cm deep. A layer of dead leaves and other detritus was added to the bottom of the tank. Bladderwort (*Utricularia* sp.) thrived in the outdoor tank and soon created a dense mat of roots and stems. The water in the outdoor tank had a pH of ~ 5.7. The group was subjected to the natural fluctuations in temperature, rainfall, and photoperiod of Columbia, South Carolina. They continued to be fed blackworms, ad lib. 3x /week and we assume that they might have also fed on the many aquatic insects and other invertebrates that colonized the tank.

The tank was checked infrequently over the winter and spring but no eggs or hatchlings were seen until 13 July 1998, when 19 hatchlings and four single eggs were found in the tank with the adults. The single eggs were attached to both *Utricularia* and plastic plants and were removed from the tank for closer observation. One of the eggs ruptured while being removed. The other three hatched four days later. The three neonates measured 13, 14, and 15 mm TL. Additional fertile eggs were observed scattered among the vegetation through August 1998. No new eggs were seen after that time. As of October 1998, there were 61 juvenile sirens in addition to the four adults, living in the tank. Roughly half of the juveniles were the same relative size as the three hatchlings measured on 17 July, and were assumed to be recently hatched.

All of the 1998 F_1 juveniles were separated from the adults and established in a plastic stock tank under identical conditions as the adults. The tank of adult sirens was again checked infrequently for eggs. No new eggs were seen until 25 June 1999 when seven eggs and 10 hatchlings were observed. On 2 August 1999 there were a total of 38 hatchlings in the tank. No eggs were seen after that date even though the females had deposited eggs through August of the previous year. Daily daytime high temperatures for the last two weeks of July had exceeded 37°C, which may have had a negative effect on reproduction. The mean weights and lengths of the largest, and presumably oldest, 1999 juveniles were 1.13 g (N = 6, range 1.01–1.31 g) and 73 mm TL (N = 6, range 69–79 mm).

The 1998 hatch F_1 sirens were near adult size in June 1999, however, no eggs or hatchlings were ever observed in the F_1 tank that year. The 1999 F_1 juveniles were separated from the adults and again maintained under identical conditions. On 18 May 2000 the mean weight of the 1999 F_1's was 1.75 g (N = 10, range 0.9–3.4 g) and total length was 91.3 mm (N = 10, range 60–123 mm).

In Spring 2000, the 0.0.4 adult founders disappeared from their tank before reproduction had begun and it was assumed that they fell victim to predation by garter snakes (*Thamnophis* sp.). A total of 0.0.12 1998 F_1's in two, separate outdoor holding tanks and 0.0.10 1999 F_1's in a single tank had been maintained outdoors since the fall of 1999. No evidence of reproduction was observed in any of these groups during 2000.

In March 2001 three 1998 F_1's weighed 4.0, 4.0, and 3.5 g and had a TL of 140 mm, 145 mm, and 150 mm, respectively. The single remaining 1999 F_1 weighed 3.5 g and had a TL of 135 mm.

Discussion.—During two breeding seasons, no fewer than 99 (61, 38) dwarf sirens were produced. Considerable mortality among the hatchlings was observed although the cause of death could not be determined. Considering the difficulty of locating the hatchlings among the dense vegetation and substrate, and how rapidly the deceased hatchlings could be consumed or decompose, the actual number of offspring produced may have been much higher. The sex ratio of the breeding group is unknown. If our initial assertion

that the group was composed of 2.2 adults is correct, then two females are capable of producing at least 61, and possibly more, offspring in a single breeding season

Hatchlings are capable of attaining near adult size in less than a year (Fig. 1). Growth rates of the sirens maintained indoors at a relatively constant temperature of 25–27°C were greater than those maintained outdoors and subjected to seasonal fluctuations in temperature. As far as we could determine, the density of hatchlings per enclosure had little effect on growth and mortality as long as there was adequate supplemental feeding.

Wild-caught *Pseudobranchus s. striatus* collected as juveniles reproduced in their fourth year. Captive conditions in earlier years might not have provided appropriate stimulus for reproduction. Nevertheless, F_1 offspring kept under identical conditions to those under which the adults bred had not yet reproduced by their third year. Two of the six original, wild-caught sirens, presumed to be 1.1, were continually housed indoors in a transparent plastic aquaria. To facilitate observation, the aquaria were maintained with clear water, few plants, and only a gravel substrate. Although this arrangement apparently did not compromise husbandry, no attempts at reproduction were ever observed. The oviposistion period for *P. striatus* was mid-June through August. The oviposition period for wild *P. axanthus* is reported to last from early November through March (Petranka 1998). The maximum length attained by a captive-raised *P. striatus* is 230 mm TL, slightly exceeding the published maximum length of 220 mm (Petranka 1998). No published data regarding longevity of *Pseudobranchus* could be found. At RZG, two captive-raised *P. s. striatus* are seven years old at the time of writing and still alive.

Unfortunately, conditions that stimulated reproduction in *Pseudobranchus*, e.g. turbid water, dense mats of vegetation and substrate, also prevented ready observation of some behaviors such as courtship and fertilization. Searching for eggs and offspring involved draining the tank, capturing the sirens and sorting through the vegetation and substrate. It was believed that this level of disturbance might compromise animal health and inhibit reproduction, hence frequent and continuous observations were not made. Nevertheless, these might represent the only observations for size and age at first reproduction as well as growth, fecundity, oviposition, and longevity for this species.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send two copies of manuscripts, double-spaced, directly to the appropriate section co-editor (addresses on inside front cover): Marc P. Hayes (lizards, amphisbaenians, crocodilians, *Sphenodon*); Charles W. Painter (amphibians); or Brian Butterfield (snakes, turtles). Authors are requested to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a Rich Text Format (RTF) version of the file. Alternatively, authors may submit manuscripts electronically, as e-mail attachments. Figures can also be submitted electronically as JPG files, although higher-resolution TIFF files may be requested for publication.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Crother (2000. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding*. Herpetol. Circ. 29:1–82); for Mexico as it appears in Liner (1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herpetol. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

AMBYSTOMA LATERALE (Blue-spotted Salamander) and ***AMBYSTOMA MACULATUM*** (Spotted Salamander). **PREDATION**. Predation by wood frog (*Rana sylvatica*) tadpoles on *A. maculatum* egg masses has been described in detail (Petranka et al. 1995. Herpetologica 54:1–13). However, nothing has been written on *R. sylvatica* predation on *A. laterale*. In Maine, all three species commonly breed in the same temporary woodland pools, where *R. sylvatica* hatch first, then *A. laterale*, then *A. maculatum*. *Ambystoma laterale* masses have fewer eggs, and are encased in jelly that is less dense than that of *A. maculatum* (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.).

On several occasions during Spring 2001, in woodland ponds in northern and central Maine, we observed *R. sylvatica* behavior that suggested preferential predation on egg masses of *A. laterale* over those of *A. maculatum*. A single predation event witnessed in captivity confirmed that *R. sylvatica* does attack and ingest larval *A. laterale*.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 32, Number 1 (March, 2001).

CAUDATA

AMBYSTOMA LATERALE (Blue-spotted Salamander). USA: MINNESOTA: Houston Co: near Houston (43°46'23.33"N, 91°29'43.19"W). 21 June 2000 and 6 July 2001. Joshua M. Kapfer and Shane N. Jones. Bell Museum of Natural History (JFBM 14237). Verified by J. J. Moriarty. First records for county (Oldfield and Moriarty 1994, Amphibians and Reptiles Native to Minnesota. Univ. Minnesota Press, Minneapolis, Minnesota. 237 pp.).

Larval individuals were collected with dip nets in June 2000 and July 2001 from the same roadside ephemeral wetland. One specimen was collected in 2000 and preserved in the field (JFBM 14237). Of the two specimens taken in 2001, one was preserved, and the other was cultured through metamorphosis in the laboratory to determine species identification. The wetland from which these specimens were collected was surrounded on three sides (west, south, and east) by mixed hardwood and conifer woodlots, with the north edge having a paved road adjacent (ca. 5 m from wetland). Dominant emergent vegetation was *Carex* sp. and dominant submergent vegetation was *Ceratophyllum* sp. The individual collected in 2000 was dip netted during daylight hours on the southern edge of the wetland. The individuals collected in 2001 were dipnetted during daylight hours from the northwestern edge of the wetland. All individuals were collected from shallow water (<0.25 m). Although the adjacent woodlots were searched, no adults were found. *Ambystoma laterale* is widely distributed in adjacent Wisconsin (Vogt 1981, Natural History of Amphibians and Reptiles in Wisconsin. Publ. Milwaukee Pub. Mus., Wisconsin. 205 pp.), occurs in an isolated population in east-central Iowa (Iowa DNR Nongame Tech. Ser. No. 3:1–24), and is found in central and northern Minnesota, with an isolated southern population 115 km to the west in Mower County (Oldfield and Moriarty, *op. cit.*).

Submitted by **JOSHUA M. KAPFER**, River Studies Center, Department of Biology, University of Wisconsin at LaCrosse, LaCrosse, Wisconsin 54601, USA (e-mail: jnjkapfer@hotmail.com), and **JEFFREY R. PARMELEE**, Department of Biology, Simpson College, Indianola, Iowa 50125, USA (e-mail: parmelee@simpson.edu).

AMBYSTOMA MACULATUM (Spotted Salamander). USA: TENNESSEE: Henry Co: floodplain woods along Nanney Road (Cowpath Road on the 1950 7.5 minute topographic quadrangle), 0.16 mi NE of Holly Fork Creek (36°23'44"N, 88°13'47"W). 28 February 2001. Bob Brinkman, Theodore Ives Jr., and Susan Fletcher. Austin Peay State University Museum (APSU 4008). Verified by A. Floyd Scott. Two adults found under logs. New county record (Redmond and Scott 1996, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. No. 12:1–94).

Submitted by **BOB BRINKMAN, THEODORE IVES JR.**, and **SUSAN FLETCHER**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

AMBYSTOMA MACULATUM (Spotted Salamander). USA: TENNESSEE: Houston Co: woodlot just E of Cedar Valley Rd. 1.0 km S of Tennessee Highway 49, 5.6 air km E of Erin (36°17'47"N, 87°38'28"W). 1 September 1999. Scott and Hunter Sutton. Austin Peay State University Museum (APSU 6050). Verified by Joseph T. Collins. Adult under decaying log. New county record (Redmond and Scott 1996, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. No. 12:1–94).

Submitted by **A. FLOYD SCOTT, SCOTT SUTTON**, and **HUNTER SUTTON**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

AMBYSTOMA MACULATUM (Spotted Salamander). USA: WISCONSIN: Jackson Co: Green Bay and Western RR right-of-way, within 75 m W of Bartell Road and ca. 100 m north of Wisc. Rt. 54, W of City Point (Sec. 34, T22N, R1E). 12 May 2001. Andrew G. Cochran and Philip A. Cochran. MPM 33142. Verified by Gary Casper. First documented record from the county (Casper 1996, Geographic Distribution of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Museum, Wisconsin). Casper (*op. cit.*) expected this species in all Wisconsin counties north of the Tension Zone, as depicted by Curtis (1959, The Vegetation of Wisconsin. Univ. Wisconsin Press, Madison); extends the known range into the Tension Zone itself.

Submitted by **ANDREW G. COCHRAN** and **PHILIP A. COCHRAN**, Biology Department, Saint Mary's University, Winona, Minnesota 55987, USA.

AMBYSTOMA TIGRINUM (Eastern Tiger Salamander). USA: TEXAS: Bastrop Co: Griffith League Ranch, a 5000-acre site owned by the Capitol Area Council of the Boy Scouts of America (30°12'58.6"N, 97°14'30.6"W). 25 May 2001. Todd Swannack and Michael R. J. Forstner. Verified by R. Kathryn Vaughn. TCWC 84707. Collected from a trap in a herpetofaunal array; new county record (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press. 421 pp.).

Submitted by **MICHELE GASTON** (e-mail: mg45447@swt.edu), **TODD SWANNACK, LEE AHLBRANDT**, and **MICHAEL R. J. FORSTNER** (e-mail: mf11@swt.edu), Department of Biology, Southwest Texas State University, San Marcos, Texas 78666, USA.

EURYCEA CIRRIGERA (Southern Two-Lined Salamander). USA: TENNESSEE: Moore Co: tributary to West Fork Mulberry Creek along Bagley Hollow Road at Charity Church (35°19'18"N, 86°28'17"W). 14 March 2001. Christine Abbey-Carlton, Susan Fletcher and Bob Brinkman. Austin Peay State University Museum of Zoology (APSU 4175). Verified by A. Floyd Scott. Two adults under rock at spring. New county record (Redmond and Scott 1996, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. No. 12:1–94).

Submitted by **CHRISTINE ABBEY-CARLTON, SUSAN FLETCHER**, and **BOB BRINKMAN**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

EURYCEA LONGICAUDA LONGICAUDA (Longtail Salamander). USA: TENNESSEE: Claiborne Co: Lincoln Memorial University campus, stream feeding Blanton Lake (36°34'50"N, 83°39'52"W). 20 April 2001. Susan Fletcher and Bob Brinkman. Austin Peay State University Museum of Zoology (APSU 4280). Verified by A. Floyd Scott. One adult under flat rock at edge of stream. New county record (Redmond and Scott 1996, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. No. 12:1–94).

Submitted by **SUSAN FLETCHER** and **BOB BRINKMAN**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

GYRINOPHILUS PORPHYRITICUS PORPHYRITICUS (Northern Spring Salamander). USA: TENNESSEE: Fentress Co: Colditz Cove State Natural Area near Northrup Falls (36°21'30"N, 84°52'19"W). 20 April 2001. Bob Brinkman and Susan Fletcher. Austin Peay State University Museum of Zoology (APSU 3262, digital photo). Verified by A. Floyd Scott. One adult and one larva found under rocks along trail leading to waterfall. New county record (Redmond and Scott 1996, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. No. 12:1–94).

Submitted by **BOB BRINKMAN** and **SUSAN M. FLETCHER**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: GEORGIA: Greene Co: Oconee National Forest at point where FS Road 1246 crosses unnamed creek, 11.3 km NW Greensboro. 21 January 2001. Matt Elliott and Stacy Smith. GMNH 46757–758. Verified by M. E. McGhee. Under logs adjacent to beaver pond. New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712).

Submitted by **MATTHEW J. ELLIOTT**, Georgia Gap Analysis Program, Institute of Ecology, University of Georgia, Athens, Georgia 30602, USA, and **STACY N. SMITH**, Warnell School of Forest Resources, University of Georgia, Athens, Georgia 30602, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: GEORGIA: Jackson Co: Boscoe Creek, adjacent to Thompson Mills State Forest, 4.8 km WNW Braselton. 4 February 2000. Stacy Smith, Rhett Jackson, and Gary Grossman. GMNH 45152. Verified by M. E. McGhee. In boggy area adjacent to stream. First vouchered county record (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1-712). Neill (1957, Copeia 1957:43–47) observed this species in Jackson County, but did not secure a voucher specimen.

Submitted by **STACY N. SMITH**, Warnell School of Forest Resources, University of Georgia, Athens, Georgia 30602, USA, and **MATTHEW J. ELLIOTT**, Georgia Gap Analysis Program, Institute of Ecology, University of Georgia, Athens, Georgia 30602, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: INDIANA: Jackson Co: Muscatatuck National Wildlife Refuge in the Muscatatuck Seep Springs Research Natural Area on Chestnut Ridge. 20 April 2001. Vicky J. Meretsky. Verified by Joseph T. Collins. University of Kansas Natural History Museum (KU Color Slides 11833–834). First county record (Minton 1972, Amphibians and Reptiles of Indiana. Indiana Acad. Sci. Monogr. 3, Indianapolis, Indiana).

Submitted by **VICKY J. MERETSKY** and **SARA M. PYLES**, School of Public and Environmental Affairs, Indiana University, Bloomington, Indiana 47405, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: TENNESSEE: Henry Co: floodplain woods along Nanney Road (Cowpath Road on the 1950 7.5 minute topographic quadrangle), 0.16 mi NE of Holly Fork Creek (36°23'44"N, 88°13'47"W). 28 February 2001. Theodore Ives Jr., Susan Fletcher, and Bob Brinkman. Austin Peay State University Museum of Zoology (APSU 4149). Verified by A. Floyd Scott. One adult under dead log. New county record and first record of the species in Tennessee west of Kentucky Lake (impounded lower Tennessee River) (Redmond and Scott 1996, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. No. 12:1–94).

Submitted by **THEODORE IVES JR.**, **SUSAN FLETCHER**, and **BOB BRINKMAN**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

HYDROMANTES PLATYCEPHALUS (Mount Lyell Salamander). USA: CALIFORNIA: Tulare Co: Sequoia National Forest, Bullfrog Lakes: NE 1/4 of NW 1/4 of section 6, T18S, R32E; 36°23'54.6"N, 118°33'10.4"W, 3365 m. 31 August 1997. Ronald Gonzales. MVZ 230238–239. Verified by Robert W. Hansen. One adult (65 mm SVL, 101 mm TL) and one subadult (43 mm SVL, 72 mm TL) found under granite slabs on bedrock and decomposed granite gravel with icemelt seepage, along creek just above upper lake. Extends range 1.8 km SSW of southernmost published locality (Franklin Pass area; Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. 2nd ed., Houghton Mifflin Co., Boston, Massachusetts. 336 pp.), but more importantly, this is the first record for the Little Kern/Kern River drainage, and southernmost record for the western slope of the Sierra Nevada.

Submitted by **RONALD GONZALES**, 921 East Kaweah Avenue, Visalia, California 93292, USA.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). USA: TENNESSEE: Moore Co: deciduous woods just East of US Highway 241, 0.3 miles N Chestnut Ridge (35°20'17"N, 86°32'05"W). 14 March 2001. Bob Brinkman, Christine Abbey-Carlton, and Susan Fletcher. Austin Peay State University Museum of Zoology (APSU 4192). Verified by A. Floyd Scott. One adult under log in woods. New county record (Redmond and Scott 1996, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. No. 12:1–94).

Submitted by **BOB BRINKMAN**, **CHRISTINE ABBEY-CARLTON** and **SUSAN FLETCHER**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

ANURA

ACRIS CREPITANS (Northern Cricket Frog). USA: TENNESSEE: Moore Co: In tributary to West Fork of Mulberry Creek along Bagley Hollow Road at Charity Church (35°19'15"N, 86°28'14"W). 14 March 2001. Christine Abbey-Carlton, Susan Fletcher, and Bob Brinkman. Austin Peay State University Museum of Zoology (APSU 4161). Verified by A. Floyd Scott. One adult collected in vegetation along edge of stream. New county record (Redmond and Scott 1996, Austin Peay St. Univ. Center for Field Biol. Misc. Publ. No. 12:1–94).

Submitted by **CHRISTINE ABBEY-CARLTON, SUSAN FLETCHER,** and **BOB BRINKMAN**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA.

AMOLOPS CREMNOBATUS (Roughback Torrent Frog). VIETNAM: Ha Tinh Province: Huong Son District, Huong Son Nature Reserve, Rao An Region, 200 m (18°22'N, 105°13'E). David Kizirian. AMNH A-161150. Verified by Nikolai Orlov. First record for Vietnam (Inger 1998, Raffles Bull. Zool. 46[1]:29–34).

Submitted by **RAOUL BAIN**, Center for Biodiversity and Conservation, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA, and **NGUYEN QUANG TRUONG**, Department of Zoology, Institute of Ecology and Biological Resources, Hoang Quoc Viet St., Cau Giay, Hanoi, Vietnam.

BUFO GLABERRIMUS: VENEZUELA: ESTADO TACHIRA: Municipio Uribante: Campamento Siberia, 28 km S Pregonero, Doradas and Uribante rivers (7°53'N, 71°45'W), 650–950 m. Colección de Vertebrados, Universidad de Los Andes, Facultad de Ciencias (CVULA-IV 3570, 3658, 3686–87, 3699, 3800, 5637, 5803 and 6302) and Unidad de Ecología y Calidad Ambiental, Compañía Anónima de Administración de Fuente Eléctrica (CADAFE), (UECA-H-28 and 147). All verified by A. Acosta. First country record and northernmost known locality. Previously reported from flanks of northern Andes in Colombia (Cochran and Goin 1970. USNM Bull. 288:113).

Submitted by **ANDRES CHACÓN-ORTIZ** and **AMELIA DIAZ DE PASCUAL**, Facultad de Ciencias, Universidad de Los Andes, Venezuela (e-mail: aecortiz@yahoo.com and adiaz@ciens.ula.ve), and **FRANCISCO GODOY**, Desarrollo Uribante Caparo, filial de CADAFE, Táchira, Venezuela (e-mail: cuencaparo@telcel.net.ve).

BUFO HOUSTONENSIS (Houston Toad). USA: TEXAS: Lee Co: 4.3 km S jct Lee County Road 331 and CR 333 on CR 333 (30°18'46.1"N, 97°09'08.9"W). 2 April 2001. James R. Dixon and Michael R. J. Forstner. Verified by R. Kathryn Vaughn. TCWC 84556. DOR; represents first recorded occurrence of this endangered species in Lee County (Dixon 2000, Amphibians and Reptiles of Texas. Second ed. Texas A&M Univ. Press. 421 pp.).

Submitted by **MICHELE A. GASTON** (e-mail: mg45447@swt.edu) and **MICHAEL R. J. FORSTNER** (e-mail: mf11@swt.edu), Department of Biology, Southwest Texas State University, San Marcos, Texas 78666, USA, and **JAMES R. DIXON**, Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas 77843, USA.

BUFO ICTERICUS (Yellow Cururu Toad). BRAZIL: GOIÁS: Municipality of Corumbá. 23 October 2000. C. Fernandes Canêdo. Centro de Estudos e Pesquisas Biológicas, Goiânia - GO (CEPB 6573, SLV 117.7 mm). Verified by M. Trefaut Rodrigues. Right bank of Corumbá River in Cerrado vegetational formation next to Corumbá Falls. Species is widespread in the Atlantic rainforest of south, eastern and southeastern Brazilian regions (Lynch 1979, The Amphibians of the Lowland Tropical Forests. *In* Duellman [ed.], The South American Herpetofauna: Its Origin, Evolution, and Dispersal, pp. 189–215; Cei 1980, Monit. Zool. Ital. [N.S.], Monogr. 2:1–609; Heyer et al. 1990, Arq. Zool. Univ. São Paulo 31[4]:231–410), usually in elevated forests but also in grassland (Kwet and Di-Bernardo 1999, Pró Mata - Anfíbios. EDIPUCRS. 107 pp.). First record for state of Goiás; expands distribution up to 600 km N (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.) and 640 km W (Haddad and Sazima 1992, Anfíbios Anuros da Serra do Japi. *In* Morellato [org.], História Natural da Serra do Japi: Ecologia e preservação de uma área florestal do Sudeste do Brasil, pp. 188–210. Unicamp Ed.) from previously known range.

Submitted by **IVAN FRANÇA E SOUZA, WILIAN VAZ SILVA, HÉLDER LÚCIO RODRIGUES DA SILVA**, and **NELSON JORGE DA SILVA, JR.**, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás, Avenida Universitária 1440, Setor Universitário, 74.210-010, Goiânia, Goiás, Brazil (e-mail [IFS]: souzai@terra.com.br).

ELEUTHERODACTYLUS JOHNSTONEI. COLOMBIA: SANTANDER: Bucaramanga (7°7'28"N, 73°06'41.6"W), 1041 m. J. Jerez, Colección Herpetológica, Museo de Historia Natural, Universidad Industrial de Santander (UIS A346–350, mean SVL = 21.79 ± 1.8 mm, N = 5). Verified by John D. Lynch. Found calling on ornamental vegetation of house gardens at east edge of city, but not in the neighboring patches of vegetation, suggesting a microhabitat preference for the frequently watered garden vegetation. Specimens of this colonizer frog are sold by gardeners and house watchmen to "adorn" yards, and in this way are dispersed to a wide residential sector of the city. Numerous specimens were captured after a complaint to the environmental authority of the city from a resident complaining of environmental contamination by the noise (calling frogs) during a rainy night. Specimens represent the second record for Colombia; extend known range of the species from Barranquilla (500 km airline).

Submitted by **JESUS E. ORTEGA, ADRIANA JEREZ**, and **MARTHA PATRICIA RAMIREZ-PINILLA**, Colección Herpetológica, Universidad Industrial de Santander, Bucaramanga, Colombia (e-mail: mpramir@uis.edu.co).

ELEUTHERODACTYLUS JUIPOCA. BRAZIL: GOIÁS: Municipality of Silvânia, Floresta Nacional de Silvânia (16°39'S, 48°36'W, 900 m). 4 April–5 May 1997. R. P. Bastos. Museu Nacional, Rio de Janeiro (MNRJ 26415–416). Verified by U. Caramaschi and C. A. G. Cruz. Previously reported from vicinity of type locality in Sousas, Campinas, São Paulo (Frost 1985, Amphibian Species of the World. A Taxonomic and Geographical Reference. Allen Press, Inc., Lawrence, Kansas. vi + 732 pp.). Also cited as occurring in Serra da Canastra (20°10'S, 46°30'W, 900–1496 m), Municipality of São Roque de Minas, Sacramento,

and, Delfinópolis, Minas Gerais (Haddad et al. 1988, Brasil Florestal 64:9–20) and Morro do Ferro (21°48'S, 46°35'W, 700 m), Municipality of Poços de Caldas, Minas Gerais (Cardoso et al. 1989, Rev. Brasil. Biol. 49[1]:241–249). First state record; extends known geographical distribution ca. 490 km to the north.

Submitted by **ROGÉRIO P. BASTOS**, Departamento de Biologia Geral, ICB, Universidade Federal de Goiás, Caixa Postal 131, 74001-970 Goiânia, Goiás, Brazil, and **JOSÉ P. POMBAL, JR.**, Departamento de Vertebrados, Museu Nacional/UFRJ, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Brazil.

ELEUTHERODACTYLUS LUTITUS. COLOMBIA: SANTANDER: Piedecuesta Municipality, corregimiento Sevilla, Estación Experimental y Demostrativa El Rasgón (7°3'N, 72°57'W), 2180 m. A. Jerez, S. Arroyo. Colección Herpetológica, Museo de Historia Natural, Universidad Industrial de Santander (UIS-A-625, 627, 645, 796, 910, 1174, 1178; SVL range 22–24 mm). Verified by John D. Lynch. Previously known only from type locality (Lynch 1984, Milwaukee Publ. Mus. Contrib. Biol. Geol. 60:10–12). Extends distribution north 108 km (airline).

Submitted by **ADRIANA JEREZ, SANDY ARROYO**, and **MARTHA PATRICIA RAMIREZ-PINILLA**, Colección Herpetológica, Universidad Industrial de Santander, Bucaramanga, Colombia (e-mail: mpramir@uis.edu.co).

ELEUTHERODACTYLUS MARNOCKII (Cliff Chirping Frog). MÉXICO: CHIHUAHUA: Grutas de Coyame, 6 km S Coyame. 22 June 1980. J. Reddell, O. McKenzie, and M. Shumate. KU 187788. Verified by Richard L. Holland. First record from México; extends known range more than 160 km from the closest reported locality in Pecos County, Texas (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.). However, if M. J. Forstner's remarks, as presented in Dixon (*op. cit.*), are correct, then all *Eleutherodactylus guttilatus* records from the Big Bend region of Texas would in reality refer to *E. marnockii*. If so, the range extension would decrease to about 25 km from the Grutas de Coyame record to the closest reported locality in Presidio County, Texas (Dixon, *op. cit*).

Submitted by **JULIO A. LEMOS-ESPINAL**, Laboratorio de Ecología, Unidad de Biología, Tecnología y Prototipos, Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autonoma de México, Apartado Postal 314, Tlalnepantla, México, México 54090 (e-mail: lemos@servidor.unam.mx), and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA (e-mail [HMS]: hsmith@spot.colorado.edu).

ELEUTHERODACTYLUS MEROSTICTUS. COLOMBIA: SANTANDER: Piedecuesta Municipality, corregimiento Sevilla, Estación Experimental y Demostrativa El Rasgón (7°3'N, 72°57'W), 2180 m. A. Jerez, S. Arroyo. Colección Herpetológica, Museo de Historia Natural, Universidad Industrial de Santander (UIS-A-622, 624, 642, 731, 734, 759, 864, 865, 915, 964, 1016, 1032, 1043; SVL range 14.4–22.64 mm). Verified by John D. Lynch. Previously known only from type locality (Lynch 1984, Milwaukee Publ. Mus. Contrib. Biol. Geol. 60:10–12). Extends distribution north 122 km (airline) on the Cordillera Oriental of the Colombian Andes.

Submitted by **ADRIANA JEREZ, SANDY ARROYO**, and **MARTHA PATRICIA RAMIREZ-PINILLA**, Colección Herpetológica, Universidad Industrial de Santander, Bucaramanga, Colombia (e-mail: mpramir@uis.edu.co).

EPIPEDOBATES BRACCATUS. BOLIVIA: SANTA CRUZ: El Portón (18°10'S, 60°08'W, ca. 550 m). 3 March 1954. Carl Gans. LACM 44399, male, SVL 25.4 mm; LACM 60976, cleared and stained, SVL 31.0 mm). Gans (1960, Ann. Carnegie Mus. 35:283–314) reported the collection of 32 specimens of *Epipedobates flavopictus* from El Portón, Santa Cruz, Bolivia, that were deposited in the MCZ (17 specimens) and CM (15 specimens). Two specimens (MCZ 29824 and CM 36155F) noted above were later donated to LACM. Silverstone (1976, Nat. Hist. Mus. Los Angeles Co., Sci. Bull. 27:1–53) reviewed the Bolivian material mentioned above and included them as a population within pattern 1 (formed by *E. braccatus* and *E. flavopictus*) of *E. pictus*. Since Silversone's publication (*op. cit.*), it has not been clear which species, *E. braccatus* or *E. flavopictus*, is present in Bolivia (Haddad and Martins 1994, Herpetologica 50:282–295; De La Riva et al. 2000, Rev. Esp. Herpetol. 14:19–164). I examined the two LACM specimens and identified them as *E. braccatus,* making them the first record from Bolivia.

EPIPEDOBATES FEMORALIS (Brilliant-thighed Poison Frog). BRAZIL: GOIÁS: Municipality of Piranhas, 5 km from Piranhas River (16°36'09"S, 51°47'49"W). 26 March 2001. D. Fenolio. Centro de Estudos e Pesquisas Biológicas, Goiânia - GO (CEPB 6575, tadpole). Collected at night in a small pond (30 m in diameter) in an anthropic area. Two young specimens were also collected (16°35'04"S, 51°47'57"W) on 29 May 2001 (CEPB 6576, SLV 13.6 mm; CEPB 6577, SLV 16.7 mm) by V. Oliveira dos Santos. All specimens were verified by M. Trefaut Rodrigues and were collected on the west bank of the Piranhas River. This species has been mentioned in descriptions of the South American herpetofauna (Duellman 1978, Univ. Kansas Mus. Nat. Hist. Misc. Pub. 65:1–352; Duellman and Salas 1991, Univ. Kansas Mus. Nat. Hist. Occ. Pap. 143:1–13; Rodriguez and Duellman 1994, Guide to the Frogs of the Iquitos Region. Lawrence, Kansas. 80 pp.) as always being found within the Amazon rainforest limits. The records reported herein come from a region previously occupied by Cerrado vegetational formation and they are the first records for the state of Goiás, expanding its distribution up to 740 km S from the previously known range (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.).

Submitted by **IVAN FRANÇA E SOUZA, WILIAN VAZ SILVA, RAFAEL SILVEIRA RIBEIRO, HÉLDER LÚCIO RODRIGUES DA SILVA**, and **NELSON JORGE DA SILVA, JR.**, Centro de Estudos e Pesquisas Biológicas, Universidade Católica de Goiás, Avenida Universitária 1440, Setor Universitário, 74.210-010, Goiânia, Goiás, Brazil (e-mail: souzai@terra.com.br).

FROSTIUS PERNAMBUCENSIS (Bromeliad Toad). BRAZIL: Bahia: Municipality of Santa Terezinha–Pedra Branca (12°51'S,

39°28'W). 17 October 1997. M. Freitas and F. A. Juncá. Laboratório de Animais Peçonhentos e Herpetologia da Universidade Estadual de Feira de Santana (LAPH-UEFS 33). Verified by O. L. Peixoto and C. A. G. da Cruz. Previously known only from the Reserva Dois Irmãos, Recife, state of Pernambuco, this little known species had its range extended ca. 170 km SW to Murici, state of Alagoas, 20 years after the original description (Peixoto and Freire 1998, Herpetol. Rev. 29:172). Herein, we report the first record in Serra da Jibóia, state of Bahia, extending the distribution of this species ca. 450 km south. As with the discovery in the state of Alagoas, this population was found at ca. 850 m, in typical Atlantic Forest vegetation.

Submitted by **FLORA ACUÑA JUNCÁ**, Departamento de Ciências Biológicas, Universidade Estadual de Feira de Santana, 44031-460 Feira de Santana, Bahia, Brazil, and **MARCOS DE FREITAS**, Grupo Ambientalista da Bahia, Avenida Lucaia, ed. Rv Center, 1o andar, Rio Vermelho, Salvador, Bahia, Brazil.

HYLA MICROPS (Nova Friburgo Treefrog). BRAZIL: BAHIA: Porto Seguro Municipality, Reserva Particular do Patrimônio Natural (RPPN) Estação Veracruz (16°23'S, 39°10'W). January 2000. D. L. Silvano. Museu Nacional at Universidade Federal do Rio de Janeiro (MNRJ 26463–64); September 2000. B. V. S. Pimenta. MNRJ 26465–66. All verified by Ulisses Caramaschi. According to Frost (1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.), distribution was the Atlantic rainforests of the southeastern region of Brazil, later extended to the state of Rio Grande do Sul (Kwet 1998, Herpetol. Rev. 29:49). Three males were collected on vegetation at the margins of a temporary pool inside the forest. New record for the state of Bahia and for northeastern Brazil; represents the northern limit of the distribution for this species.

Submitted by **DÉBORA L. SILVANO** (e-mail: dsilvano@softhome.net) and **BRUNO V. S. PIMENTA** (e-mail: brunopimenta@softhome.net), Laboratório de Manejo de Fauna, D. Zool./ICB, Universidade Federal de Minas Gerais, 31270-901, Belo Horizonte, Minas Gerais, Brazil.

HYLA NANA. BRAZIL: RIO GRANDE DO SUL: Municipality of Itaqui: nearness Ibicui River bridge at BR 472 Road (29°20'S, 56°38'W). Between December 1999 and January of 2001. L. O. M. Giasson and S. T. Z. Cechin. Herpetology Collection, Departamento de Biologia, Universidade Federal de Santa Maria, Santa Maria (ZUFSM 2355–56, 2710–12). Verified by P. C. A. Garcia and C. F. B. Haddad. No previous voucher specimen for this frog was available from the state of Rio Grande do Sul, despite its being widespread in adjacent areas of Argentina and Uruguay (Klappenbach and Langone 1992, Anales del Museo Nacional de Historia Natural 8:163–222).

Submitted by **LUÍS O. M. GIASSON**, Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, C. P. 199, 12506-900, Rio Claro – SP, Brazil (e-mail: olimpio@biologo.mailbr.com.br) and **SONIA T. Z. CECHIN**, Departamento de Biologia, Universidade Federal de Santa Maria, faixa de camobi, km 9, campus, Camobi, cep: 97105-900, Santa Maria, Rio Grande do Sul, Brazil (e-mail: cechinsz@ccne.ufsm.br).

HYLA PRASINA (Burmeister´s Treefrog). BRAZIL: RIO GRANDE DO SUL: São José dos Ausentes, Silveira (28°50'S, 50°00'W), Fazenda Cachoeirão dos Rodrigues (ca. 1200 m). 18 February 2001. A. Kwet and T. Miranda. Museu de Ciências e Tecnologia da PUCRS, Porto Alegre, Brazil (MCP 4613–14). Verified by M. Di-Bernardo. This new record for the state of Rio Grande do Sul represents the southernmost locality known for this species in the mountains of southeastern Brazil (Minas Gerais, Rio de Janeiro and São Paulo) and extends known distribution ca. 300 km south from previous records. Two males were found calling at a pond in syntopy with abundant *Hyla pulchella*, *H. minuta* and *Pseudis cardosoi*.

Submitted by **AXEL KWET**, Zoologie, Staatliches Museum für Naturkunde Stuttgart, Rosenstein 1, D-70191 Stuttgart, Germany (e-mail: axel.kwet@uni-tuebingen.de), and **TATIANA MIRANDA**, Laboratório de Pesquisas Biológicas, PUCRS, Avenida Ipiranga, 6681, CEP 90619-900 Porto Alegre, Brazil (e-mail: tatimiran@hotmail.com).

HYLA SENICULA (Corcovado Treefrog). BRAZIL: BAHIA: Porto Seguro Municipality, Reserva Particular do Patrimônio Natural (RPPN) Estação Veracruz (16°23'S, 39°10'W). March 2000. B. V. S. Pimenta and P. H. C. Cordeiro. Museu Nacional at Universidade Federal do Rio de Janeiro (MNRJ 25622–24). Verified by Ulisses Caramaschi. Published distribution for the species is the coastal region of Rio de Janeiro and Espírito Santo states (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.) and the continental state of Minas Gerais (Caramaschi and Cruz 1996, Herpetol. Rev. 27:208–209). Specimens were collected on perches at the margins of a pool on the borders of a forest after heavy rain; northernmost record for the species.

Submitted by **BRUNO V. S. PIMENTA** (e-mail: brunopimenta@softhome.net) and **DÉBORA L. SILVANO** (e-mail: dsilvano@softhome.net), Laboratório de Manejo de Fauna, D. Zool./ICB, Universidade Federal de Minas Gerais, 31270-901, Belo Horizonte, Minas Gerais, Brazil.

HYLA SOARESI. BRAZIL: GOIÁS: Municipality of Mambaí (14°29'S; 46°06'W, 709 m). 3 March 2001. R. F. Juliano and R. Lingnau. Museu Nacional, Rio de Janeiro (MNRJ 26417). Verified by U. Caramaschi and C. A. G. Cruz. Previously recorded from states of Piauí, Picos, Ceará, Santana do Cariri, Paraíba, Areia Branca, Minas Gerais, Manga (Gomes and Peixoto 1996, Iheringia, ser. Zool. 80:33–38) and Bahia and Jandaíra (Gomes and Peixoto 1991, Acta Biol. Leopoldensia 13:141–162). First state record; extends known distribution ca. 270 km to west.

Submitted by **RAFAEL F. JULIANO**, **RODRIGO LINGNAU**, and **ROGÉRIO P. BASTOS**, Departamento de Biologia Geral, ICB, Universidade Federal de Goiás, Caixa Postal 131, 74001-970 Goiânia, Goiás, Brazil, and **JOSÉ P. POMBAL JR.**, Departamento de Vertebrados, Museu Nacional/UFRJ, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Brazil.

PHYLLODYTES MELANOMYSTAX. BRAZIL: SERGIPE: Serra de Itabaiana, Municipality of Areia Branca (10°45'S, 37°19'W, 160 m). 10 May 1997. C. M. Carvalho. Museu de Zoologia, Universidade de São Paulo (MZUSP 88968–969). Verified by José P. Pombal, Jr. Previously known only from type-

locality on the southern coast of the state of Bahia, Brazil (Caramaschi et al. 1992, Copeia 1992:187–191; Frost 2000, Amphibian Species of the World: An Online Reference V2.20 [1 September 2000] http://research.amnh.org/herpetology/index.html] First state record; extends range NW ca. 350 km airline from the type-locality and range west ca. 50 km airline from the coast line.

Submitted by **ULISSES CARAMASCHI**, Departamento de Vertebrados, Museu Nacional/UFRJ, Quinta da Boa Vista, 20940-040 Rio de Janeiro, Rio de Janeiro, Brazil, and **OSWALDO LUIZ PEIXOTO**, Departamento de Biologia Animal, Universidade Federal Rural do Rio de Janeiro, 23851-970 Seropédica, Rio de Janeiro, Brazil.

PLEURODEMA THAUL (Sapito de Cuatro Ojos). ARGENTINA: NEUQUEN: Departamento Minas: W shore of Laguna Superior de Epulafquen, 36°49'30"S, 71°5'48"W, ca. 1400 m. 21 January 2000. Carmen Úbeda. Museo de Ciencias Naturales de La Plata, La Plata, Argentina (MLP A. 2274). Juvenile specimen collected in a shallow pond near a temperate deciduous forest of roble pellín (*Nothofagus obliqua*). Juveniles were also present 3 km W in La Negra pond. CHUBUT: Departamento Río Senguer: Land between La Plata and La Plata Chico lakes, 72°00'S, 44°48'50"W, ca. 1000 m. 12 January 2000. Carmen Úbeda. Mature female (SVL 47 mm). (MLP A. 2275). Specimen was collected in a *Sphagnum* peat bog in a cold-temperate humid deciduous forest of lenga (*Nothofagus pumilio*). Tadpoles and juveniles were also present. Both verified by Néstor G. Basso. Species is known from Chile and Argentina, with a narrow distribution area along the eastern slopes of the Andes, and occupies a variety of habitats. In Chile, it is distributed from Río Copiapó (III Region) to Aysen Province (XI Region) (Cei 1962, Batracios de Chile. Ediciones de la Universidad de Chile, Santiago de Chile. 128 pp. + cviii). In Argentina, it has been reported, without coordinate precision, for "the Andean-Antarctic region, from the high valleys of Neuquén (Neuquén River) to upper Chubut" (Cei 1980, Amphibians of Argentina. Monit. Zool. ital. [N.S.] Monogr. 2:[i–xii] + 1–609). The two records reported herein represent new latitudinal extremes for distribution east of the Andes. The Laguna Superior de Epulafquen locality represents the northern and warmer manifestation of the Andean-Patagonic forests east of the Andes, where *P. thaul* co-exists with *Bufo spinulosus*. The La Plata lake locality represents a forest with cold and very humid conditions, where the species co-exists with *Batrachyla antartandica* and *Bufo variegatus*.

SPHAENORHYNCHUS PALUSTRIS. BRAZIL: BAHIA: Porto Seguro Municipality, Reserva Particular do Patrimônio Natural (RPPN) Estação Veracruz (16°23'S, 39°10'W). March 2000. B. V. S. Pimenta and P. H. C. Cordeiro. Museu Nacional at Universidade Federal do Rio de Janeiro (MNRJ 25592–94); September 2000. B. V. S. Pimenta. Coleção Célio F. B. Haddad (CFBH 3702–03) at Universidade Estadual Paulista (UNESP-Rio Claro). All verified by Ulisses Caramaschi. Species was known only from the type locality, Sooretama at Linhares, Espírito Santo (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.); represents a new record for the state of Bahia. Specimens were found in a pool at the borders of a forest on emerging vegetation. Discovery of this population extends the distribution of this species to the north ca. 302 km.

Submitted by **BRUNO V. S. PIMENTA** (e-mail: brunopimenta@softhome.net) and **DÉBORA L. SILVANO** (e-mail: dsilvano@softhome.net), Laboratório de Manejo de Fauna, D. Zool./ICB, Universidade Federal de Minas Gerais, 31270-901, Belo Horizonte, Minas Gerais, Brazil.

TESTUDINES

APALONE MUTICA CALVATA (Gulf Coast Smooth Softshell). USA: ALABAMA: Perry Co: Cahaba River, 1 km upstream (north) of County Road 6 crossing. 29 June 2001. Peter V. Lindeman. Verified by Joseph T. Collins. KU Color Slide 11832. Gravid adult female (SCL 269 mm) captured in the act of digging a nest cavity on a flat sand and gravel beach. New county record (Mount 1975, The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **PETER V. LINDEMAN**, Department of Biology and Health Services, 150 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail: plindeman@edinboro.edu.

APALONE MUTICA MUTICA (Midland Smooth Softshell). USA: ARKANSAS: Hempstead/Miller County line: vic. Fulton off US Rt. 67 at Red River access. 8 July 2001. Timothy L. Eddings. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 26236). Verified by Stanley E. Trauth. New county record for Hempstead; extends range 18 km NW of previous localities in the Red River watershed of Arkansas (Trauth et al., in prep., The Amphibians and Reptiles of Arkansas). Species has also been reported from neighboring Bossier and Caddo parishes, Louisiana (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.). Interestingly, there are as yet no records of this turtle from adjacent NE Texas (Dixon 2000, Amphibians and Reptiles of Texas. Second Ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **CHRIS T. McALLISTER** and **TIMOTHY L. EDDINGS**, Department of Biology, Texas A&M University-Texarkana, Texarkana, Texas 75505, USA.

HYDROMEDUSA TECTIFERA (South American Snakeneck Turtle). BRAZIL: Rio de Janeiro: Duque de Caxias: Cidade das Meninas (2 juvs). 8 October 1941. A. Passarelli. Museu Nacional, Brazil (MNRJ 1049); October 1944. A. Passarelli. MNRJ 2483. City of Niterói: São Francisco. 1923. MNRJ 3792. All verified by Ronaldo Fernandes. Easternmost records for the species and first records for the state of Rio de Janeiro, where it lives in sympatry with *Hydromedusa maximilliani* (Ernst and Barbour 1989, Turtles of the World. Smithsonian Institution, Washington).

DIXON**, Texas Cooperative Wildlife Collection, Texas A&M University, College Station, Texas 77843, USA, and **LEE SHERROD**, Horizon Environmental Services, Inc., Austin, Texas 78716, USA.

MACROCHELYS TEMMINCKII (Alligator Snapping Turtle). USA: FLORIDA: Franklin Co: St. Vincent Island (St. Vincent National Wildlife Refuge), Rattlesnake Slough at Oyster Pond, (N29.64383° W85.14850°). 15 August 2000. Thomas E. Lewis. Sternberg Museum of Natural History, Ft. Hays State University, Hays, Kansas (MHP 6811). Verified by Lisa K. Irwin. Adult male found dead on margin of dried up freshwater pond. Sex determination based on combination of size (ca. 455 mm median straight-line carapace length) and presence of an intercostal fontanelle distance ca. 35–40 mm (Pritchard 1989, The Alligator Snapping Turtle: Biology and Conservation. Publ. Milwaukee Pub. Mus., Milwaukee. 104 pp.). Carapace exhibited evidence, based on scrapes and gouges in the scutes and one instance of bone perforation, of either pre- or post-mortem predation/scavenging by *Alligator mississippiensis*. Syntopic species associates observed at this locality in January 2000 included *Apalone ferox*, *Pseudemys nelsoni*, and *Alligator mississippiensis*. Definitively establishes first record for interior freshwater pond system of St. Vincent Island and first record for Apalachicola Bay Barrier Islands (Blaney 1971, Herpetologica 274:406–430; Christman 1984. Natural History of St. Vincent Island, Florida. Progress Rep. No. 1, covering the period January 1983–December 1983. Unpubl. Report. Denver Wildl. Res. Center Ecol. Section, Gainesville, Florida. 25 pp.). On 8 April 1997, T. E. Lewis found the skeletal remains of an adult individual at West Pass Beach (N29°37.8268' W85°06.7558') on St. Vincent Island, an outlet from Apalachicola Bay into the Gulf of Mexico. The carapace measured 620 mm (median curved carapace length) and was missing most of the scutes, although the skull was present and still attached to shell (KU Color Slides 11828–11831). Verified by Joseph T. Collins and Travis W. Taggart. We speculate that this occurrence is a result of post-mortem transport by currents out of the Apalachicola River and/or Bay and does not represent an individual from the island population. This species has been reported as inhabiting brackish waters; however, the locality at West Pass is generally considered to be hyper-saline.

Submitted by **THOMAS E. LEWIS**, St. Vincent National Wildlife Refuge, P.O. Box 447, Apalachicola, Florida 32329, USA, and **KELLY J. IRWIN**, Arkansas Game and Fish Commission, 915 East Sevier Street, Benton, Arkansas 72015, USA; e-mail: kirwin@agfc.state.ar.us.

TERRAPENE NELSONI KLAUBERI (Northern Spotted Box Turtle). MEXICO: CHIHUAHUA: mountains on N side of Arroyo El Camuchil, Batopilas, 435 m. 17 July 2000. Julio A. Lemos-Espinal. Herpetological collection of Unidad de Biología, Tecnología y Prototipos (UBIPRO 5921–22). Verified by Richard L. Holland. First records for Chihuahua and a slight range extension eastward from Guirocoba, Sonora (Smith and Smith 1979, Synopsis of the Herpetofauna of Mexico, Vol. VI: Guide to Turtles, Bibliographic Addendum III. John Johnson, North Bennington, Vermont. xviii + 1044 pp.).

Submitted by **JULIO A. LEMOS-ESPINAL**, Laboratorio de Herpetología, UBIPRO, Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autonoma de México, Apartado Postal 314, Avenida de los Barrios s/n, Los Reyes Iztacala, Tlalnepantla, Estado de México, 54090 México (e-mail: lemos@servidor.unam.mx), and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA; e-mail (HMS): hsmith@spot.colorado.edu.

TRACHEMYS SCRIPTA (Slider). USA: TEXAS: Lee Co: 3.6 km W jct. Lee County Road 310 and CR 309 on CR 309 (30°20'46.1"N, 97°06'52.7"W). 20 April 2001. Michele Gaston, Ellen Gaston, James R. Dixon, and Michael R. J. Forstner. Verified by R. Kathryn Vaughn. TCWC 84560–61. Collected AOR; new county record (Dixon 2000, Amphibians and Reptiles of Texas.

Second Ed. Texas A&M University Press. 421 pp.).

LACERTILIA

BACHIA FLAVESCENS. VENEZUELA: ESTADO AMAZONAS: Helipuerto 4 (H4), Alto Río Orinoco (02°05'N, 64°05'W), 290 m. 26 October 1991. Nélida Abab. Museo de la Estación Biológica de Rancho Grande (MEBRG 2645). Captured under leaf litter on forest floor; Helipuerto 5 (H5), 5 km N Río Orinoco (02°14'35"N, 64°02'32"W), 410 m. 22 October 1991. César Molina. Museo de Historia Natural La Salle (MHNLS 14121). Captured under leaf litter on forest floor near small creek. All verified by Gilson Rivas. First state records; previously known only from Bolívar (Gorzula and Señaris 1998, Scientia Guaianæ 8:1–270 pp. + 32 color plates). These new records suggest that this taxon has a wider distribution in Venezuela than was previously suspected.

Submitted by **CÉSAR MOLINA**. Museo de Historia Natural La Salle, Sección de Herpetología, Apartado postal 1930, Caracas 1010-A, Venezuela; e-mail: crmolina@mixmail.com.

BACHIA GUIANENSIS. VENEZUELA: ESTADO BOLÍVAR: Marabá (06°19'10"N, 63°31'35"W), 290 m. 15 May 1992. César Molina. Museo de Historia Natural La Salle (MHNLS 14565). Captured in soil under leaf litter in a gallery forest near a creek. Verified by Gilson Rivas. Partially fills gap in distribution between Gurí (07°46'N, 63°00'W) (Hoogmoed and Dixon 1977, Zoologische Mededelingen 51[2]:25–31), Hato La Yeguera, 18 km E El Manteco (07°23'N, 62°24'W, 230 m) (Gorzula and Señaris 1998, Scientia Guaianæ 8:1–270 pp. + 32 color plates), and the Serranía de los Pijiguaos in Bolívar (06°10'N, 66°50'W, 650 m) (Señaris 1998, Amphibia-Reptilia 19:303–310).

Submitted by **CÉSAR MOLINA**, Museo de Historia Natural La Salle, Sección de Herpetología, Apartado postal 1930, Caracas 1010-A, Venezuela; e-mail: crmolina@mixmail.com.

CERCOSAURA OCELLATA OCELLATA (Black-striped Shade Lizard). VENEZUELA: ESTADO BOLÍVAR: Reserva Forestal de Imataca, (07°31'N, 61°08'W) 180 m. 15 May 1990. Luis Balbas. Museo de la Estación Biológica de Rancho Grande (MEBRG 2712–13). Extends known distribution east ca. 160 km (Gorzula and Señaris 1998, Scientia Guaianæ 8:1–270 pp. + 32 color plates). ESTADO AMAZONAS: Cerro Parú (04°34'N, 65°30'W) 480 m. Mario Palacios. Museo de Historia Natural La Salle (MHNLS 12032). Both verified by Gilson Rivas. First state record and the southwesternmost locality in Venezuela, extending the distribution ca. 465 km from the nearest locality (Gorzula and Señaris 1998, *op. cit.*). These new records suggest that this taxon has a wider distribution in Venezuela than was previously suspected.

Submitted by **CÉSAR MOLINA**. Museo de Historia Natural La Salle, Sección de Herpetología, Apartado postal 1930, Caracas 1010-A, Venezuela; e-mail: crmolina@mixmail.com.

CNEMIDOPHORUS LACERTOIDES. ARGENTINA: BUENOS AIRES: Partido de Bahía Blanca: Bahía Blanca (38°44'S, 62°15'S). 25 March 2001. C. H. F. Perez and C. M. Grassini. Fundación Miguel Lillo Herpetological Collection, San Miguel de Tucumán, Argentina (FML 10359). Verified by L. J. Avila. Southernmost citation for this poorly known teiid species; extends known range 100 km SW of La Ventana Mountains (Cei 1993, Mon. XIV, Mus. Reg. Sci. Nat. Torino. 949 pp). The lizard was found in a human-disturbed site, inside urban limits of Bahia Blanca City along a railroad edge with dumped debris and scattered small shrubs of exotic and native plants.

Submitted by **CRISTIAN HERNAN FULVIO PEREZ**, Agustin Alvarez 1182 A, 8000, Bahía Blanca, Buenos Aires, Argentina (e-mail: liolaemu@criba.edu.ar), and **CARLOS MARIO GRASSINI**, Cátedra de Biología General, Departamento de Biología, Bioquímica y Farmacia, Universidad Nacional del Sur, San Juan 640, 8000 Bahía Blanca, Buenos Aires, Argentina.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). USA: ILLINOIS: Henry Co: Mineral Marsh State Nature Preserve (41°26'36"N, 89°53'14"W). 7 June 2001. R. Todd Bittner. INHS 17395. Verified by Christopher A. Phillips. DOR. Incomplete specimen (head and tail missing) salvaged from dirt truck path. A live individual was also observed at the site, which is a degraded sand prairie. New county record (Phillips et al. 1999, Field Guide to Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Manual 8:1–282).

Submitted by **TONYA D. BITTNER**, P.O. Box 34, Bradford, Illinois 61421, USA, and **R. TODD BITTNER**, Illinois Department of Natural Resources, Division of Natural Heritage, IVCC E. Campus Building 11, 815 North Orlando Smith Road, Oglesby, Illinois 61348-9691, USA (e-mail: tbittner@theramp.net).

COLEODACTYLUS SEPTENTRIONALIS (Pigmy Gecko). VENEZUELA: MONAGAS: Municipio Sotillo: Campamento El Merey, Morichal del río Uracoa, 09°00'N, 62°21'W, 30 m. 5 April 1989. Ramón Rivero. Museo de la Estación Biológica de Rancho Grande, Venezuela (EBRG 2322). Verified by J. Celsa Señaris. Adult female collected on leaf litter at 1205 h. First record for Estado Monagas and North Orinoco River. Another record for Venezuela reported from Los Castillos de Guayana, state of Delta Amacuro, 08°31'N, 62°22'W, 50 m (Avila-Pires 1995, Zoologische Verhandelingen 299:1–706). Donoso-Barros (1968, Carib. J. Sci. 8[3–4]:105–121] and Rivero-Blanco (1967 "1968," Mem. Soc. Cienc. Nat. La Salle 77:103–119) mentioned *C. meridionalis* for "La Gran Sabana," and for "San Pedro de las Bocas, La Paragua," 06°53'N, 62°52'W (state of Bolívar), respectively, although we think these specimens are probably *C. septentrionalis*. However, the specimens reported by Donoso-Barros (*op. cit*) apparently lack vouchers, thus it is difficult to confirm their identity.

Submitted by **GILSON RIVAS FUENMAYOR** (e-mail: gilsonrivas@mixmail.com) and **CESAR R. MOLINA** (e-mail: crmolina@mixmail.com), Museo de Historia Natural La Salle, Sección de Herpetología, Apartado Postal 1930, Caracas 1010-A, Venezuela.

HEMIDACTYLUS TURCICUS TURCICUS (Mediterranean Gecko). MÉXICO: CHIHUAHUA: La Perla (28°18'21.4"N, 104°33'7.3"W), 1610 m. 8 August 2000. Julio A. Lemos Espinal. Herpetological collection of Unidad de Biología, Tecnología y Prototipos (UBIPRO 6341–49). Verified by Richard L. Holland. First record for Chihuahua (McCoy 1970, Cat. Amer. Amphib. Rept. 87:1–2), although predicted in the Coyame area (Morafka 1977, A Biogeographic Analysis of the Chihuahuan Desert Through Its Herpetofauna. Biogeographica, Vol. IX., Dr. W. Junk B. V. Publs., The Hague. viii + 313 pp.).

Submitted by **JULIO A. APOSTOLEPIS QUIROGAI. BRAZIL: RIO GRANDE DO SUL: Municipality of Santo Ângelo (28°18'S, 54°08'W). 16 March 2001. L. H. Cappellari. Verified by Marcos Di-Bernardo. Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul (MCP 12185). First state record; extends known range 180 km SE from Posadas, Misiones, Argentina (Giraudo and Scrocchi 1998, Herpetologica 54:470–476).

Submitted by **THALES DE LEMA** and **LIZE HELENA CAPPELLARI**, Laboratório de Herpetologia, Departamento de Biologia, Faculdade de Biociências, Pontifícia Universidade Católica do Rio Grande do Sul, Avenida Ipiranga, 6681, CEP 90619-900, Porto Alegre, Rio Grande do Sul, Brazil.

BOA CONSTRICTOR IMPERATOR (Mexican Boa Constrictor). MÉXICO: CHIHUAHUA: Arroyo El Camuchil, Batopilas (27°01'34.1"N, 107°45'44.5"W), 435 m. 14 July 2000. Julio A. Lemos-Espinal. Herpetological collection of Unidad de Biología, Tecnología y Prototipos (UBIPRO 5901). Verified by Richard L. Holland. First record for Chihuahua; extends range 45 airline km ENE of Sierra de Choix, Sinaloa (USNM 46503) reported by Smith (1943, Proc. U.S. Nat. Mus. 93:393–504).

Submitted by **JULIO A. LEMOS-ESPINAL**, Laboratorio de Herpetología, UBIPRO, Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autonoma de México, Apartado Postal 314, Avenida de los Barrios s/n, Los Reyes Iztacala, Tlalnepantla, Estado de México, 54090 México (e-mail: lemos@servidor.unam.mx), and **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0334, USA (e-mail [HMS]: hsmith@spot.colorado.edu).

COLLORHABDIUM WILLIAMSONI (Williamson's Reed Snake). MALAYSIA: PENINSULAR MALAYSIA: Selangor-Pahang border, Genting Highlands (3°46'N, 101°47'E), ca. 1750 m). May 2001. Oh Kim Sang. Raffles Museum of Biodiversity Research: Zoological Reference Collection (ZRC.2.4997, SVL 190 mm; total length 217 mm). Verified by Kelvin K. P. Lim. Previously known from only two montane localities: Maxwell's Hill (Perak) and Cameron Highlands (Perak-Pahang border) (Tweedie 1983, The Snakes of Malaya. Third Ed. Singapore National Printers. 167 pp.); represents a southeasterly range extension of ca. 130 km (from Cameron Highlands).

Submitted by **TZI MING LEONG**, Department of Biological Sciences, National University of Singapore, Singapore 119260 (e-

mail: scip0132@nus.edu.sg), and **BOO LIAT LIM**, Department of Wildlife and National Parks (Peninsular Malaysia), Km 10, Jalan Cheras, 561000 Kuala Lumpur, Malaysia.

CONIOPHANES BIPUNCTATUS (Two-spotted Snake). COSTA RICA: HEREDIA: 38 km NE Puerto Viejo de Sarapiquí, Tres Marías, northern Caribbean versant. 1996. Miguel Solano. University of Costa Rica Museum of Zoology (UCR 13039); ca. 13 km S Puerto Viejo de Sarapiquí, La Conquista. 5 June 2001. Alejandro Solórzano. UCR 15400. Both verified by Gerardo Chaves. First records for Costa Rica (Savage and Villa R. 1986, Herpetofauna of Costa Rica. SSAR Contrib. Herpetol. 3:1–207). These records also bridge a distributional gap between Nicaragua and Panamá (Villa et al. 1988, Middle American Herpetology: A Bibliographic Checklist. Univ. Missouri Press, Columbia. i-xxxv + 131 pp.). UCR 13039 was found in lowland rainforest and UCR 15400 was DOR on highway connecting Puerto Viejo and Río Frío.

Submitted by **ALEJANDRO SOLÓRZANO**, Serpentario Nacional, P.O. Box 2157-1002, San José, Costa Rica; e-mail: asolorz@racsa.co.cr.

DIADOPHIS PUNCTATUS (Ringneck Snake). USA: LOUISIANA: St. Martin Parish: Sherburne Wildlife Management Area, Happy Town Road, ca. 0.4 km E Louisiana Rt. 975. 27 April 2001. Chris Wanko. Discovered in mesic, bottomland hardwood forest. LSUMZ 83635. Verified by Jeff Boundy. First record for parish (Dundee and Rossman, 1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp).

Submitted by **MICHAEL A. SEYMOUR**, 9150 Ventura Drive, Baton Rouge, Louisiana 70815-8855, USA; e-mail: caprimulgus@earthlink.net.

LAMPROPELTIS MEXICANA (San Luis Potosí Kingsnake). MÉXICO: AGUASCALIENTES: Municipality of San José de Gracia: Arroyo Los Timones, 1 km S of Santa Rosa (22°01'14" N, 102°34'30" W), 2352 m. 10 October 1998. Héctor Avila Villegas, J. Jesús Sigala Rodriguez, and Gustavo Ernesto Quintero Díaz. Museo de Zoología "Alfonso L. Herrera" Facultad de Ciencias, UNAM (MZFC 13655); same area (22°01'13"N, 102°34'23"W), 2350 m. 11 October 1998. Gabriel González Adame. Museo de Zoología, Departamento de Biología, Universidad Autónoma de Aguascalientes (UAA-VR 273). Both specimens verified by Hobart M. Smith. First records for Aguascalientes; extend range ca. 74.3 km south of the previous northern record (MCZR 162279) from 2.74 km south of Troncoso, Zacatecas (Liner and Dundee 1977, Herpetol. Rev. 8:85). Both specimens were found in oak savanna and are referable to the "greeri" population as characterized by Webb (1961, Copeia 1961:326–333) and Garstka (1982, Breviora 466:1–35).

LIOPHIS FESTAE. BRAZIL: PARÁ: Santarém (54°42'W, 2°26'S), right bank of the Amazonas River, locality São Braz. 2001. S. Santos. Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós (LPHA 1558). Verified by Andrei G. Guedes. Previously known from Ecuador and Peru. First record for Brazil; increases known distribution ca. 2815 km by airline from the nearest record (2°30'S, 80°00'W) in Peru (2000, Dixon, Copeia 2000:482–490).

Submitted by **JOSSEHAN GALÚCIO DA FROTA** (e-mail: jgfrota@mailbr.com.br) and **RUBENS NOBUO YUKI**, Linha de Pesquisa em Herpetologia da Amazônia, Faculdades Integradas do Tapajós, Rua Rosa Vermelha 335, Santarém, Pará, Brazil, CEP: 68.010-200.

MASTIGODRYAS BODDAERTI. BRAZIL: GOIÁS: Municipality of Campinaçu, E bank Maranhão River (14°03'34"S, 48°29'72"W). 27 February 1997. C. Amaral Souza. Centro de Estudos e Pesquisas Biológicas, Goiânia - GO (CEPB/SM 26118, SVL 1180 mm, body weight: 165 g). Verified by M. Trefaut Rodrigues. Specimen was found in a gallery forest within the Cerrado vegetational formation. During the faunal rescue operation (Operação Lobo Guará), owing to the flooding of Serra da Mesa hidroeletric power plant reservoir, this taxa was collected in significant numbers by the rescue staff from October 1996 to December 1998, in all the municipalities affected by the reservoir flooding (Niquelândia, Minaçu, Uruaçu, Campinorte, Colinas do Sul, and Barro Alto). Species has been mentioned in comments about the South American Herpetofauna (Gasc and Rodrigues 1980, Bull. Mus. natn. Hist. nat., Paris, 4ª série, 2, A [2]:559–598; Cunha and Nascimento 1978, Publ. Avuls. Mus. Paraense E. Goeldi, n° 102:1–20; Lancini 1986, Serpientes de Venezuela, [E. Armitano Ed.], 262 pp.; Pérez Santos and Moreno 1988, Boll. Mus. reg. Sci. Nat. Torino. 517 pp.), as having its distribution limited in the Amazon Basin Rainforest to Colombia, Bolivia, French Guiana, Venezuela, Ecuador, and Brazil. It was also reported to be present in the northern part of the Atlantic forest (Dixon 1979, *In* Duellman [ed.], The South American Herpetofauna: Its Origin, Evolution, and Dispersal, pp. 217–240) and as an isolated colony in the state of Bahía, Brazil (Peters and Orejas 1986, The Catalogue of Neotropical Squamata Part I. Revised Ed. Smithsonian Institution. 293 pp.). The presence of this taxon in Brazil was also reported in Manaus, INPA/WWF Reserves, Samuel and Balbina hydroeletric power plants in the state of Amazonas, and in the Tucuruí power plant in the state of Pará (Silva and Sites 1995, Conserv. Biol. 9[4]:873–901). In Rondônia, this species was observed in an open vegetational formation similar to Cerrado vegetational province called *Capoeira*. Specimen reported herein is the first record for the state of Goiás; extends geographic distribution of this taxa 1815 km SE (Vanzolini 1986, Levantamento Herpetológico as àrea do Estado de Rondônia sob a Influência da Rodovia BR 364,

Relatório de Pesquisa 1, Brasília: CNPq, Assessoria Editorial. 50 pp.) and 1035 km S (from Pará) (Silva and Sites 1995, *op. cit.*) from previously known range limits.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). THAILAND: RAYONG PROVINCE: Ko Samet (Samet Island). 27 March 2001. Patrick Grootaert (PG field no. 21026). IRSNB 15597. Verified by Van Wallach. DOR being attacked by ants when found in the morning on a forest path near a cliff overhanging the sea by about 50 m. First island record and second provincial record (Niyomwan 1999, Species Diversity, Morphology and Habitat Types of Blind Snakes [Family Typhlopidae] in Thailand. Master of Science Thesis, Dept. Biology, Faculty of Science, Chulalongkorn University, Bangkok. vi +141 pp. [in Thai with English summary]). In Thailand, species has already been recorded from 36 of the 76 provinces scattered over the country, but not yet from Roi Et and surrounding provinces in the easternmost part (Niyomwan, *op. cit.*). This is probably due to a lack of collecting effort there, because *R. braminus* is widely distributed in the area just east of Thailand, such as Cambodia and Laos (Welch 1988, Snakes of the Orient: A Checklist. Krieger Publ. Co., Malabar, Florida. vii + 183 pp.).

SPILOTES PULLATUS MEXICANUS (Tropical Rat Snake). MÉXICO: HIDALGO: Municipality of Huejutla, Chalahuiyapa, ca. 5.5 km NE of Huejutla (20°08'N, 98°25'W), 170 m. 8 March 1998 and 22 March 1999. Baltazar Hernández-Hernández. Verified by Sol de Mayo A. Mejenes-Lopéz. Colección Herpetológica, Instituto Tecnólogico Agropecuario de Hidalgo (ITAH 120, 125). Adult and juvenile males found dead, the former in tropical deciduous forest and the latter in an adjacent pasture; Municipality of Orizatlán, on highway San Felipe-Huejutla ca. 2.3 km E San

Felipe Orizatlán (21°N, 98°W), 160 m. 4 October 1999. Felipe Barragán-Torres. Verified by Sol de Mayo A. Mejenes-López. ITAH 326. A juvenile found DOR in secondary vegetation. First state records for species and bridges three distributional gaps of 1) ca. 56 and 85 km SE respectively, from the closest known locality in San Luis Potosí (Taylor 1953. Univ. Kansas Sci. Bull. 35:1587–1614), 2) ca. 70 and 96 km SW respectively, from the closest known locality in Veracruz (Pérez-Higareda and Smith 1991, Ofidiofauna de Veracruz, Análisis Taxonómico y Zoogeográfico. Publ. Espec. Inst. Biól. UNAM 7:122), and 3) ca. 160 km SW of the closest locality in Tamaulipas (Smith and Taylor 1945, USNM Bull. 187:1–239).

Submitted by **FERNANDO MENDOZA-QUIJANO** (e-mail: mendozaq@mail.ibiologia.unam.mx) and **BALTAZAR HERNÁNDEZ-HERNÁNDEZ**, Instituto Tecnolólogico Agropecuario de Hidalgo, Km 5.5 Carr. Huejutla-Chalahuiyapa, Apartado Postal 94, Caixa Postal 43000, Huejutla de Reyes, Hidalgo, México.

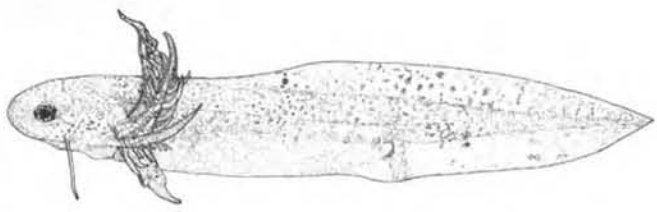
STENORRHINA DEGENHARDTI. VENEZUELA: ESTADO BARINAS: Barinitas, 550 m. 14 July 2001. H. Sánchez. Colección de Vertebrados, Universidad de los Andes, Mérida (CVULA 6312). Verified by Yoel Morales. Previous authors (Roze 1966, La taxonomía y Zoogeografía de los Ofidios de Venezuela. Ediciones de la Biblioteca, Univ. Central de Venezuela, Caracas; Lancini 1979, Serpientes de Venezuela. Armitano Ed. Caracas; Lancini and Kornacker 1986, Die Schlangen von Venezuela. Verlag Armitano, Caracas) considered this species confined to the coastal range. First record for the state and the Andes; westernmost record in Venezuela. Habitat was rainforest in Andean piedmont. Biogeographically, area shares elements from different bio-regions: Amazonian, Andean, Llanos, and Coastal range (see Barrio 1998, Acta Biol. Venezuela 18[2]:1–93 for a biogeographic view).

Submitted by **CESAR L. BARRIO**, Fundación AndígenA, Apartado Postal 210, Mérida 5101-A, Venezuela (e-mail: cesarlba@yahoo.com) and **DANIEL CALCAÑO**, Serpentario Los Llanos, Barinitas, Barinas, Venezuela (e-mail: reprecal@cantv.net).

STENORRHINA FREMINVILLII (Alacranera). MÉXICO: MICHOACÁN: Colola, Marine camp (near sea turtle nesting beach). 23 September 1977. Clayton J. May. UTEP 12461. Verified by Carl S. Lieb. First record for Michoacán, extending known range ca. 383 km NW of Acapulco, Guerrero (MVZ 78757).

Submitted by **JERRY D. JOHNSON** (e-mail: jjohnson@utep.edu) and **ROBERT G. WEBB**, Department of Biological Sciences, University of Texas at El Paso, El Paso, Texas 79968, USA.

STORERIA DEKAYI (Brown Snake). USA: WISCONSIN: Jackson Co: DOR, Wisconsin Rt. 54, ca. 5 km E of North Bend (Sec. 24, T19N, R6W). 13 October 2000. Andrew G. Cochran, Joseph A. Cochran, and Christopher D. Knight. MPM 33146; Green Bay and Western RR right-of-way at Bartell Road, ca. 100 m N of Wisconsin Rt. 54, W of City Point (Sec. 34, T22N, R1E). 26 April 2001. Philip A. Cochran. MPM 33143. Both specimens verified by Gary Casper. These records, from opposite ends of the county (ca. 62 km apart), substantiate an earlier record from the SE corner of the county based on a specimen not examined by Vogt (1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Museum, Wisconsin). Casper (1996, Geographic Distribution of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Museum, Wisconsin) stated that *S. d. texana* and *S. d. wrightorum* intergrade in a band that passes through Wood County immediately to the east. Although both Jackson County specimens had a dorsal pattern typical for *S. d. texana*, the North Bend snake had a dark vertical streak posterior to the eye, similar to *S. d. dekayi*, whereas the City Point snake had a dark horizontal temporal line, similar to *S. d. limnetes* (Conant and Collins 1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. xx + 450 pp.).



Submitted by **ANDREW G. COCHRAN**, **PHILIP A. COCHRAN**, **JOSEPH A. COCHRAN**, and **CHRISTOPHER D. KNIGHT**, Biology Department, Saint Mary's University, Winona, Minnesota 55987, USA.

Additions to the Mozambique Herpetofauna: Two New Lizards from the Namuli Massif

BILL BRANCH
Port Elizabeth Museum, P.O. Box 13147
Humewood 6013, South Africa
e-mail: pemwrb@zoo.upe.ac.za

and

PETER G. RYAN
Percy FitzPatrick Institute, University of Cape Town
Rondebosch 7701, South Africa
e-mail: pryan@botzoo.uct.ac.za

The herpetofauna of central and northern Mozambique is poorly known. The early studies of Peters (1882) were mainly restricted to coastal areas and the Lower Zambezi region, as have other more recent studies (Broadley 1990, 1992). The Namuli Massif (15°22'S, 37°02'E) is the largest mountain range in northern Mozambique and forms the main watershed for the region (Vincent 1933a). The nearest montane area of similar stature is Mount Mulanje, southeastern Malawi, some 160 km to the southwest. The Namuli Massif is a series of spectacular granitic outcrops that tower over the relatively flat, 800 m high plateau of northern Mozambique. The highest peak, Mount Namuli, is 2412 m high, and several other peaks are over 2200 m.

Few faunal collections have ever been made from the Namuli Massif. Vincent (1933a) gives a general account of the region visited when he collected birds in northern Mozambique during 1931–1932 (Vincent 1933b, 1936). As part of a survey (November–December 1998) of the avifauna of the Namuli massif (Ryan et al. 1999), three lizards were collected opportunistically. As two represent important additions to the herpetofauna of Mozambique, they are described below.

Chamaeleonidae

Rampholeon platyceps (Mulanje Leaf Chameleon). ZAMBEZIA PROVINCE: Ukalini Forest, Namuli Massif (15°22'S, 37°04'E, ca. 1550 m). 30 November 1998. PEM R14921. An adult female collected by a local guide in the forest that nestles under the south face of the main Namuli peak. Previously considered endemic to the sub-montane seasonal rain forests of Mt. Mulanje (1000–1800 m), although a population is also known from Mchese Mountain, adjacent to Mt. Mulanje (Tilbury, pers. comm.). The Namuli specimen inhabits similar habitat and is the first record of the species from Mozambique.

The female is gravid with seven almost spherical eggs (largest diameter 4.1–4.5 mm, four in the left oviduct and three in the right oviduct) that lack obvious embryonic development. The stomach contained insect fragments, including a coleopteran elytra.

Another small chameleon, possibly referable to this species, was seen being carried by a Crowned Hornbill *(Tockus alboterminatus)* that was flying over the canopy of Ukalini Forest on 29 November.

Gekkonidae

Lygodactylus rex (Regal Dwarf Gecko). ZAMBEZIA PROVINCE: ridge leading up to the knife-edge Murukuni Ridge, Namuli Massif (15°22'S, 37°03'E; 1800 m). 30 November 1998. PEM R14922. An adult female collected on rock in an open grassy area adjacent to the Ukalini Forest on the south flank of Mt. Namuli. The habitat comprises a large granite whaleback with shallow, dry peaty soil that, after a prolonged dry period, had pulled back in areas from the rock. Another individual, presumed to be the same species, was seen on a dead tree stump in similar habitat bordering the forest edge on the southern flank of Peseni at 2000 m (15°23'S, 37°02'E) on 3 December 1998.

No new material of this species has been reported since its description from Lujeri, Mt. Mulanje (Broadley 1963). The Namuli specimen differs in a number of features from the type series; i.e., in having 8 not 7 upper and lower labials, three postmentals (usually two), and only two nasals (usually three). In addition, the distinctive eyespot above the shoulder (Broadley 1963) is very reduced in extent and intensity in the Namuli female. Broadley (in litt. May 1999) notes that in Mulanje material both sexes have a white spot above the shoulder, and in males this has a broad black border which makes it very conspicuous. The Namuli female is the first record for Mozambique.

Scincidae

Mabuya varia (Variable Mabuya). ZAMBEZIA PROVINCE: southern flank of Peseni, Namuli Massif (15°23'S, 37°02'E; 2000 m). 3 December 1998. PEM R14923. An adult female. This species was common in habitat similar to that of *Lygodactylus rex*, from at least 1500 m to 2000 m elev.

We are aware of no other herpetological collections from the Namuli region. Two of the three lizards in the current small collection are new records for Mozambique. Both specimens show subtle variation from the Mulanje populations, and further material is required to assess whether these differences are consistent and worthy of taxonomic recognition. It is probable that other Malawi endemics (e.g., *Platysaurus mitchelli*, *Lygodactylus bonsi*, *Proscelotes mulanjensis*, and *Chamaeleo mulanjensis*) occur in the montane grasslands and relict forests of the Namuli massif.

Acknowledgments.—We thank Don Broadley (Bulawayo) and Colin Tilbury (Jwaneng) for their comments on the Namuli material. Carlos Bento, Callan Cohen, John Graham, Vincent Parker, and Claire Spottiswoode conducted the avifaunal survey with PGR and assisted with the capture of reptiles.

New County Records of Amphibians and Reptiles from Indiana

ROBERT BRODMAN
Biology Department, Saint Joseph's College
Rensselaer, Indiana 47978, USA
e-mail: bobb@saintjoe.edu

Distribution records of amphibians and reptiles of Indiana have been documented by Minton (1972) and Minton et al. (1982). However, distribution records are lacking in many sections of Indiana. Voucher specimens of new county records are reported here from Adams, Jay, Miami, Fulton, Floyd, Posey, Dubois, Spencer, Monroe, Owen, Daviess, Sullivan, and Greene counties. Identification of *Ambystoma* was verified electorphoretically by James P. Bogart. All other specimens were verified by Alan Resetar. All voucher specimens, call recordings, and color photographs are deposited in the Saint Joseph's College zoological collection (SJCAM = amphibians; SJCRP = reptiles). Unless otherwise noted, all specimens were collected by the author.

Caudata

Ambystoma jeffersonianum (Jefferson Salamander). ADAMS Co: Hanna-Nuttman Park. 2 April 1999. SJCAM 201. Four larvae taken and raised to metamorphosis in the lab; several egg masses seen in the field. All four specimens from this site were LJJ triploids. WELLS Co: Ouabache State Park. 23 March 2000. Robert Brodman SJCAM 240. Five larvae taken and raised to metamorphosis in the lab; two were JJ and three were LLJ. Many egg masses seen in the field.

Ambystoma laterale (Blue-spotted Salamander). JAY Co: Bell-Croft Woods Nature Preserve. 12 April 1999. SJCAM 202. Five larvae taken and raised to metamorphosis in the lab; several more seen. Four were LJJ triploids and one was a pure LL diploid. Extends the range ca. 80 km south of Steuben County and east of Kosciusko County.

Ambystoma opacum (Marbled Salamander). OWEN Co: Jordan Seeps Nature Preserve. 27 February 2000. SJCAM 203. Two larvae taken. Fills distribution gap in northwest Indiana between Monroe and Vigo counties.

Ambystoma texanum (Small-mouthed Salamander). SPENCER Co: Bloomfield Barrens Nature Preserve. 4 March 2000. SJCAM 204. Five larvae taken and raised to metamorphosis in the lab; dozens of egg masses seen in the field. Extends range into southcentral tip of the state. SULLIVAN Co: 1 km W of Minnehaha Fish and Wildlife Area. 19 March 2000. SJCAM 205. Five larvae taken; three were raised to metamorphosis in the lab. Extends the range ca. 50 km west of Cass County and ca. 70 km northeast of Warren County. GREENE Co: 1 km E of Hillenbrand Fish and Wildlife Area. 23 April 2000. SJCAM 206. Five larvae taken and raised to metamorphosis in the lab. The Greene and Sullivan county records fill the gap between records from the southwest and west central sections of the state. WELLS Co: Ouabache State Park. 23 March 2000. SJCAM 241. Two adult males taken from breeding pond. STARKE Co: Koontz Lake Nature Preserve. 28 April 2001. SJCAM 248. Four larvae taken and raised to metamorphosis in the lab. Fills gap between between Jasper, LaPorte, and Marshall counties.

Ambystoma tigrinum (Eastern Tiger Salamander). JAY Co: Bell-Croft Woods Nature Preserve. 12 April 1999. SJCAM 207. Four larvae taken; many others seen. SULLIVAN Co: 1 km W of Greene-Sullivan State Forest. 19 March 2000. SJCAM 208. Four larvae taken; dozens of egg masses seen. Fills gap between Vigo and Knox counties. FULTON Co: Lake Manitou. 2 April 1999. SJCAM 238. One adult taken from the road. WELLS Co: Ouabache State Park. 23 March 2000. SJCAM 242. Two larvae taken and raised to metamorphosis in the lab. Many egg masses seen in the field.

Hemidactylium scutatum (Four-toed Salamander). STARKE Co: Koontz Lake Nature Preserve. 28 April 2001. SJCAM 249. Four adults were seen under logs; two were taken. Fills gap between between LaPorte and Marshall counties.

Plethodon glutinosus (Northern Slimy Salamander). STARKE Co: Koontz Lake Nature Preserve. 28 April 2001. SJCAM 250. Four adults and three juveniles were seen under logs; two were taken. Fills gap between between Jasper, Porter and Marshall counties.

Notophthalmus viridescens (Eastern Newt). FLOYD Co: Hardin Ridge Nature Preserve. 24 February 2000. SJCAM 209. Two voucher specimens taken; many more seen. Fills gaps between Harrison and Clark counties.

Siren intermedia (Lesser Siren). SULLIVAN Co: 1 km W of Minnehaha Fish and Wildlife Area. 23 June 2000. SJCAM 210. One adult was taken from a pond. Fills gap between Greene, Knox and Vigo counties.

Anura

Bufo americanus (American Toad). STARKE Co: Jasper-Pulaski Fish and Wildlife Area. 9 April 1998. SJCAM 246. Two adult males taken from two medium sized choruses. Completes series in northwest Indiana.

Bufo fowleri (Fowler's Toad). SULLIVAN Co: 1 km S of Minnehaha Fish and Wildlife Area. 23 April 2000. SJCAM 212. One adult was taken from the road. Fills gap between Greene, Knox, and Vigo counties.

Scaphiopus holbrookii (Eastern Spadefoot). OWEN Co: Watasch Lake. 25 June 2000. SJCAM 239. A small chorus was videotaped. Extends the range northeast and fills a gap between Bartholemew and Vigo counties.

Acris crepitans (Northern Cricket Frog) ADAMS Co: Hanna-Nuttman Park. 2 April 1999. SJCAM 213. One adult taken from a pond. Fills gaps between Wells and Jay counties. MIAMI Co: 1 km S of Frances Slocum State Forest. 11 May 1999. SJCAM 213. One adult taken from a small chorus. Fills gaps between Fulton and Wabash counties. GREENE Co: 1 km E of Hillenbrand Fish

and Wildlife Area. 23 April 2000. SJCAM 214. One adult male taken from a large chorus. Fills gap between adjacent counties.

Pseudacris crucifer (Spring Peeper). ADAMS Co: Hanna-Nuttman Park. 2 April 1999. SJCAM 215. One adult male taken from a moderate sized chorus. Fills gaps between Allen and Jay counties. DUBOIS Co: Buffalo Pond Nature Preserve. 25 February 2000. SJCAM 216. One adult male taken from a large chorus. Fills gap among adjacent counties. GREENE Co: 1 km E of Hillenbrand Fish and Wildlife Area. 23 April 2000. SJCAM 217. One adult male taken from a large chorus. Fills gap between adjacent counties. SPENCER Co: Bloomfield Barrens Nature Preserve. 4 March 2000. SJCAM 218. One adult male taken from a small chorus. Fills gap between Warrick and Perry counties.

Pseudacris triseriata (Western Chorus Frog). WELLS Co: Ouabache State Park. 23 March 2000. SJCAM 243. One adult male taken. Three large choruses and two small choruses were heard. Fills gaps between Huntington, Adams and Jay counties.

Hyla chrysoscelis (Cope's Gray Treefrog). POSEY Co: Twin Swamps Nature Preserve. 27 May 2000. SJCAM 219. One adult male taken from a moderate sized chorus. The chorus was audiotaped. DAVIESS Co: 1 km W of Glendale Fish and Wildlife Area. 30 May 2000. SJCAM 220. One adult male AOR. SULLIVAN Co: 1 km S of Minnehaha Fish and Wildlife Area. 23 April 2000. SJCAM 221. One adult male taken from a small chorus. The chorus was audiotaped. GREENE Co: 1 km E of Hillenbrand Fish and Wildlife Area. 23 April 2000. SJCAM 222. One adult male taken from a small chorus. The chorus was audiotaped. These records nearly complete a series in southwestern Indiana.

Hyla versicolor (Eastern Gray Treefrog). STARKE Co: Koontz Lake Nature Preserve. 28 April 2001. SJCAM 247. Two medium sized choruses were heard and one adult male was taken. Completes a series in northwest Indiana.

Rana catesbeiana (Bullfrog). FULTON Co: Lake Manitou. 6 June 1999. SJCAM 223. One adult taken from small chorus. Extends range into the Upper Wabash Valley. MONROE Co: Lemon Lake. SJCAM 224. One adult taken from small chorus. DAVIESS Co: 1 km W of Glendale Fish and Wildlife Area. 30 May 2000. SJCAM 225. One juvenile taken AOR. SULLIVAN Co: 1 km S of Minnehaha Fish and Wildlife Area. 23 April 2000. SJCAM 226. One adult was taken from a small chorus. GREENE Co: 1 km E of Hillenbrand Fish and Wildlife Area. 23 April 2000. SJCAM 227. One adult male taken from a small chorus. These records nearly complete a series in southwestern Indiana.

Rana clamitans (Green Frog). ADAMS Co: Hanna-Nuttman Park. 2 April 1999. SJCAM 228. One adult male taken from a puddle. WELLS Co: Ouabache State Park. 24 June 2001. SJCAM 244. One adult male taken from a large chorus. MIAMI Co: 1 km S of Frances Slocum State Forest. 11 May 1999. SJCAM 229. One adult taken from a small chorus. These records complete a series in northeast Indiana. DAVIESS Co: 1 km W of Glendale Fish and Wildlife Area. 30 May 2000. SJCAM 230. One adult male taken AOR. SULLIVAN Co: 1 km S of Minnehaha Fish and Wildlife Area. 23 April 2000. SJCAM 231. One adult was taken AOR. GREENE Co: 1 km E of Hillenbrand Fish and Wildlife Area. 23 April 2000. SJCAM 232. One adult male taken from a small chorus. SPENCER Co: Bloomfield Barrens Nature Preserve. 4 March 2000. SJCAM 233. One adult male taken from a small chorus. These records nearly complete a series in southwestern Indiana.

Rana pipiens (Northern Leopard Frog). WELLS Co: Ouabache State Park. 24 June 2001. SJCAM 245. One adult male taken from a small chorus. Completes a series in northeast Indiana.

Rana sylvatica (Wood Frog). FULTON Co: Manitou Island Conservation Area. 2 April 1999. SJCAM 234. One adult taken from small chorus. Fills the gap between Marshall and Cass counties. DAVIESS Co: 4 km N of Glendale Fish and Wildlife Area. 26 February 2000. SJCAM 235. One adult male taken AOR. Fills the gap between Martin and Knox counties. POSEY Co: 2 km SE of Harmonie State Park. 3 March 2000. SJCAM 236. One adult female taken AOR. FLOYD Co: Brock-Sampson Nature Preserve. 24 February 2000. SJCAM 237. One adult male taken from a small chorus. These records fill gaps in the distribution along the Ohio river.

Testudines

Chrysemys picta (Painted turtle). SULLIVAN Co: Greene-Sullivan State Forest. 23 June 2000. SJCRP 201. One adult male was seen and photographed AOR. GREENE Co: Greene-Sullivan State Forest. 29 May 2000. SJCRP 202. One juvenile was captured and photographed in a roadside ditch. DAVIESS Co: Glendale Fish and Wildlife Area. 30 May 2000. SJCRP 203. One male was seen and photographed in a pond.

Terrapene carolina (Eastern Box Turtle). SULLIVAN Co: 2 km W of Dugger. 23 June 2000. SJCRP 204. Male was seen and photographed AOR. SPENCER Co: Bloomfield Barrens Nature Preserve. 29 May 2000. SJCRP 205. One female was seen and photographed along edge of woods and corn field. DAVIESS Co: Capehart Sand Flat Nature Preserve. 30 May 2000. SJCRP 206. One male was seen and photographed in a mud patch. DUBOIS Co: 2 km NW of Buffalo Pond Nature Preserve. 28 May 2000. SJCRP 207. One female was seen and photographed along the edge of the road.

Lacertilia

Eumeces fasciatus (Five-lined Skink). SPENCER Co: Bloomfield Barrens Nature Preserve. 29 May 2000. SJCRP 208. One male seen and photographed while it ate winged termites emerging from a log.

Serpentes

Diadophis punctatus (Northern Ringneck Snake). STARKE Co: Koontz Lake Nature Preserve. 19 June 2001. Robert Brodman and Michael Parrish. SJCR 209. One adult taken from a rotting log. Fills a gap between Fulton and Porter counties in northern Indiana.

Nerodia sipedon (Northern Water Snake). SULLIVAN Co: 1 km W of Greene-Sullivan State Forest. 23 June 2000. SJCRP 210. DOR male.

Thamnophis sirtalis (Common Garter Snake). DUBOIS Co: 1 km W of Buffalo Pond Nature Preserve of Greene-Sullivan State Forest. 30 May 2000. SJCRP 211. DOR juvenile.

The Texas Natural History Collection (TNHC) of the Texas Memorial Museum of Science and History (TMMSH) currently contains over 60,000 dry, frozen, and fluid preserved amphibian and reptile specimens. Although the collection contains significant holdings from localities around the world (notably southeast Asia, Africa, and South America), the majority of specimens in the TNHC are from Texas. Of these 35,000+ Texas specimens, most were collected between the mid-1940's and late 1960's by W. Frank Blair and his students from localities throughout the state, including significant and sizable collections from Brewster, Hutchinson, Presidio, Terrell, and Travis Counties. In the spring of 1999, a National Science Foundation Collections Improvement Grant was awarded to the TMMSH for the verification of all TNHC specimens cataloged prior to 1991 (the date from which new collection information was kept on computer databases). This grant has allowed us to verify not only the presence of these specimens within the TNHC, but to verify and examine the associated locality information from the written ledgers that served as the official record from the 1940's until 1991. To date, we have verified over 52,000 specimens, including all Texas specimens in the collection (Texas specimens cataloged after 1991 included as well). As a result, we have discovered 33 new Texas county records which either fill in distributional gaps or expand the known ranges of certain taxa (Dixon 2000). Information regarding the holdings of the TNHC can be found at

http://www.utexas.edu/depts/tnhc/herps/

Specific inquiries can be directed to David Cannatella at catfish@mail.utexas.edu or Jessica Rosales, collections manager, at rosales@mail.utexas.edu. It should also be noted that the herpetological holdings of Texas Tech University (TTU; 11,500 specimens) were acquired by the TNHC in March 2001; the TTU data and specimens will be incorporated into the main collection during the 2001–02 academic year.

Caudata

Ambystoma maculatum (Spotted Salamander). TITUS CO: SWEPCO site on Swauano Creek near Cason. 18 September 1973. J. Grubb. TNHC 55414.

Ambystoma opacum (Marbled Salamander). TITUS CO: SWEPCO site on Swauano Creek near Cason. 21 June 1973. J. Grubb. TNHC 55413.

Plethodon albagula (Western Slimy Salamander). WALKER CO: New Waverly, 11 mi NW in Sam Houston National Forest. 7 October 1950. UT Zoology 336 Class. TNHC 12079.

Anura

Bufo americanus (American Toad). COOKE CO: Muenster, ca. 10 mi NNE. 6 April 1991. J. H. Yantis. TNHC 55542–55.

Bufo debilis (Green Toad). CALDWELL CO: Luling, 5.7 mi N on Hwy [likely U.S. Hwy 183]. 15 May 1951. R. W. Axtell et al. TNHC 14199. DICKENS CO: FM 193, 4.7 road mi W King County line (also 10 road mi E FM 265 on FM 193). 30 June 2000. T. LaDuc. TNHC 60350. GUADALUPE CO: Kingsbury, 2 mi NW. 19 June 1962. No collector given. TNHC 30969.

Bufo punctatus (Red-spotted Toad). ERATH CO: Thurber, 3 mi SW at old coal mine. 7 July 1950. Allen and Mann. TNHC 12489–96.

Bufo speciosus (Texas Toad). REAL CO: Near Leakey. 31 August 1958. R. Worthington. TNHC 28973.

Eleutherodactylus marnockii (Cliff Chirping Frog). CALDWELL CO: Lockhart, 4 mi NE. 14 Novmber 1953. Trevino. TNHC 20753.

Hyla squirella (Squirrel Treefrog). ATACOSA CO: Lytle, 7 mi SE, on Kirn Ranch. 8 July 1949. Miller. TNHC 7270–2.

Pseudacris crucifer (Spring Peeper). TITUS CO: SWEPCO site on Swauano Creek near Cason. 20 June 1973. J. Grubb. TNHC 55405; SWEPCO site on Swauano Creek near Cason. 18 September 1973. J. Grubb. TNHC 55406; SWEPCO site on Swauano Creek near Cason. 19 June 1973. J. Grubb. TNHC 55411.

Pseudacris streckeri (Strecker's Chorus Frog). CHEROKEE CO: Jacksonville, ditches along 1601 Canada Street. 26 December 1979. K. Tedin and J. Sharp. TNHC 49850–63; no specific locality. 26 December 1979. K. Tedin. TNHC 49965–77. TITUS CO: SWEPCO site on Swauano Creek near Cason. 28 March 1974. J. Grubb. TNHC 55407 (2 specimens). WALLER CO: Brookshire, 6 mi W. 25 May 1957. Hermes. TNHC 28889.

Pseudacris triseriata (Western Chorus Frog). TITUS CO: SWEPCO site on Swauano Creek near Cason. 19 June 1973. J. Grubb. TNHC 55412.

Rana berlandieri (Rio Grande Leopard Frog). JACKSON CO: Ganado, 12.5 mi E. 24 October 1964. Adler. TNHC 57288.

Rana palustris (Pickerel Frog). RUSK CO: Owens and Barnhardt Creeks, N of Nacogdoches. February 1962. C. Hubbs. TNHC 49255.

Rana sphenocephala (Florida Leopard Frog). ATACOSA CO: Lytle, 7 mi SE on Kirn Ranch. 26 February 1949. Blair. TNHC 5729. Same locality. 15–16 October 1949. UT Zoology 336 class. TNHC 9259.

Scaphiopus hurterii (Hurter's Spadefoot). TITUS CO: SWEPCO site on Swauano Creek near Cason. 28 March 1974. J. Grubb. TNHC 55392–5; SWEPCO site on Swauano Creek near Cason, "old field." 19 June 1973. J. Grubb. TNHC 55419–23; SWEPCO site on Swauano Creek near Cason. 25 May 1973. J. Grubb. TNHC 55425. WALLER CO: Monaville. 27 April 1959. M. D. Sabath. TNHC 30920.

Testudines

Terrapene ornata (Ornate Box Turtle). STONEWALL CO: U.S. Rt. 83, 5.8 mi N jct with U.S. Rt. 380, 33°15'43"N, 100°14'53"W. 7 May 1995. A. H. Price. TNHC 55601.

Lacertilia

Eumeces obsoletus (Great Plains Skink). FANNIN CO: Honey Grove. 1 May 1959. Tamsitt. TNHC 26172.

Eumeces septentrionalis (Prairie Skink). HOUSTON CO: Crockett, 2.5 mi W, Halls Bluff Road, Spence Ranch. 8 April 1950. Wootters. TNHC 28852.

Eumeces tetragrammus (Four-lined Skink). CULBERSON CO: Guadalupe Mts., 2 mi NNW Pine Springs in "The Bowl," 8000+ ft. elev. 2 June 1953. Mecham. TNHC 16289–90; Guadalupe Mts., "The Bowl" near Pine Springs. 29 April 1953. Mecham. TNHC 17993–18000.

Sceloporus olivaceus (Texas Spiny Lizard). ANGELINA CO: Rockland, 3 mi N. 16 October 1965. J. Baker. TNHC 50040; MONTGOMERY CO: FM 1097, 2 mi W FM 149 [on] William Gay Ranch. 3 October 1965. R. McKown. TNHC 50042.

Sceloporus variabilis (Rose-bellied Lizard). CALDWELL CO: Palmetto State Park, Ottine. 27 November 1964. Slama. TNHC 46334.

Serpentes

Arizona elegans (Eastern Glossy Snake). AUSTIN CO: U.S. Rt. 90, 2 mi W Brazos River. 27 June 1960. M. D. Sabath. TNHC 29255.

Coluber constrictor (Eastern Racer). HOUSTON CO: Crockett, 3 mi W [on] Halls Bluff Road. 6 June 1958. Willingham. TNHC 28707.

Crotalus atrox (Western Diamondback Rattlesnake). CRANE CO: Crane, 5 mi S. 8 June 1959. M. D. Sabath. TNHC 29040.

Drymarchon corais (Western Indigo Snake). GOLIAD CO: FM 2442, 3.5 road mi SW Texas Rt. 239. 25 August 1999. T. LaDuc. TNHC 60228. Specimen collected as heavily scavenged DOR.

Nerodia cyclopion (Mississippi Green Water Snake). POLK CO: near Livingston. May 1963. Mitchell. TNHC 28921.

Acknowledgments.— We thank J. H. Malone for verifying the identity of all specimens whose records are presented here (save *Eumeces septentrionalis,* confirmed by T. Reeder) and J. R. Dixon for verifying that the records reported herein are in fact new. This work was supported by NSF Grant 9876830.

New Records of Squamate Reptiles in Central Brazilian Cerrado II: Brasília Region

CRISTIANO DE CAMPOS NOGUEIRA
Departamento de Ecologia, Universidade de São Paulo
R. do Matão, 321, trav. 14. CEP 05508-900
São Paulo, São Paulo, Brazil

The Cerrado is the second largest Neotropical ecosystem, covering over 2,000,000 km^2 in central Brazil (Eiten 1972). However, this region remains poorly known in zoological terms (Colli et al. 1998). Species lists providing voucher specimens for central Brazilian squamate reptiles are available only in Amaral (1935) and Hoge (1952a, b). The central Brazilian Cerrado harbors a rich but poorly studied squamate fauna, deserving intensive and detailed field work and research. Such studies are even more compelling due to the ongoing high rates of destruction of the Cerrado's natural landscapes.

New distributional records of squamate reptiles for central Brazil are presented herein as partial results of squamate diversity studies started in 1997 in the Brasília region, encompassing an area of 100 km radius from the center of Brasília. Some additional records in the northeastern state of Goiás (Paranã River valley and Chapada dos Veadeiros regions) are also included. A snake species list for the Brasília region is available in Silva and Sites (1995), including some taxa treated herein. However, the presence of these taxa in the studied area was only confirmed in the present study, after the designation of voucher material. According to unpublished preliminary results, and based also on the records presented herein, the Brasília region (31,400 km^2; 100 km radius around Brasília, excluding Chapada dos Veadeiros and Paranã valley regions, NE Goiás state) harbors a rich squamate fauna composed of over 90 squamate reptiles, including at least 63 snakes (CN, unpublished data), 24 lizards (G. R. Colli, pers. comm.), and four amphisbaenians.

The present study adds to the list of new records for central Brazil in the Emas National Park region (Valdujo and Nogueira 2001). All records are based on specimens deposited in the herpetological collections of Instituto Butantan (IB, verified by F. L. Franco), Museu de Zoologia da Universidade de São Paulo (MZUSP, verified by C. C. Mello and P. E. Vanzolini) and Coleção Herpetológica da Universidade de Brasília (CHUNB, verified by G. R. Colli).

Amphisbaenia

Amphisbaena anaemariae. DISTRITO FEDERAL: Brasília municipality, Área Alfa (Brazilian navy training area) in arboreal savanna (cerrado sensu-stricto), 16°00'S, 47°56'W, 1100 m elev. C. Nogueira and P. H. Valdujo. 8 December 2000. MZUSP 88130. Previously known only from the type series, collected in Serra da Mesa region, and from a specimen collected in Anápolis, both in the state of Goiás (Vanzolini 1997). Although this species has recently been recorded for Nova Ponte and Indianápolis in Minas Gerais (Vrcibradic and Soares 1999), thereby extending the range ca. 500 km S of Brasília, this specimen is the first record of the species in Distrito Federal and fifth known locality record for the

taxon.

Amphisbaena mensae. DISTRITO FEDERAL: Brasília municipality, Área Alfa (Brazilian navy training area) in arboreal savanna (cerrado sensu-stricto) and sparse savanna (campo cerrado), 16°00'S, 47°56'W, 1100 m elev. 11 January 2000. P. H. Valdujo and C. Nogueira. MZUSP 88127; 18 May 2000. C. Nogueira. MZUSP 88129; 17 May 2000. C. Nogueira. MZUSP 88131. This taxon is known only from type locality, in Minaçu, Serra da Mesa region, northeastern Goiás (Castro-Mello 2000). Our specimens extend range 250 km S of type locality.

Leposternon microcephalum. DISTRITO FEDERAL: Brasília municipality, disturbed site close to cerrado grassland (campo sujo), close to Água Limpa farm, 15°54'S, 47°57'W, 1050 m. 20 November 2000. C. Nogueira and P. H. Valdujo. MZUSP 88123. Extends range ca. 600 km NW of Rio das Velhas (close to Belo Horizonte, Minas Gerais) and ca.1000 km W of Andaraí, in the Chapada Diamantina region (Gans 1971), both in the borders of the Cerrado domain.

Lacertilia

Enyalius bilineatus. DISTRITO FEDERAL: Brasília municipality, Área Alfa (Brazilian navy training area), inside gallery forest of Saia Velha River, 16°00'S, 47°56'W, 1050 m elev. 22 October 1999. C. Nogueira. CHUNB 21813 and 21815. First record for central Brazil and northernmost record for the species. Extends range ca. 600 km NW of nearest locality, Lagoa Santa, Minas Gerais, southeastern Brazil (Jackson 1978).

Colobosaura modesta. DISTRITO FEDERAL: Brasília municipality, Área Alfa (Brazilian navy training area), inside gallery forest of Saia Velha River, 16°00'S, 47°56'W, 1050 m elev. 20 October 1999. C. Nogueira. CHUNB 21806. 24 October 1999. C. Nogueira. CHUNB 21807. First records for central Brazil, extending range ca. 450 km NW of nearest locality, Morro da Garça, Minas Gerais (Vanzolini 1977).

Serpentes

Leptotyphlops koppesi. MINAS GERAIS: Unaí municipality, Fazenda Cafundó, 16°15'S, 47°03'W, 615 m elev., in disturbed area close to sparse savanna (campo cerrado). 30 September 1999. C. Nogueira. CHUNB 20348. Known only from type locality (Peters and Orejas-Miranda 1970; McDiarmid et al. 1999) and from the Emas National Park region (Valdujo and Nogueira 2001). The present record extends distribution ca. 650 km NE of Emas National Park.

Boiruna maculata. GOIÁS: Terezina de Goiás municipality, Paranã River valley region, northeastern Goiás. GO 118 Highway, Km 253, close to 13°36'S 47°11'W, near Amutafo River, Paranã tributary. 1 January 2000. C. Nogueira and P. H. Valdujo. CHUNB 20375. Extends range ca. 550 km N of Ouvidor, nearest known locality in Goiás and former northernmost record for the species (Zaher 1996). DISTRITO FEDERAL: Brasília municipality. Collector unknown. CHUNB 03853 and 03863.

Drymoluber brazili. DISTRITO FEDERAL: Brasília municipality. 1 November 1988. Collector unknown. CHUNB 03748. Previously known only from southcentral Brazil. Extends range ca. 450 km N of Uberaba, Minas Gerais, southeastern Brazil, type locality for the species (Peters and Orejas-Miranda 1970).

Helicops modestus. DISTRITO FEDERAL: Brasília municipality, Planaltina. 10 October 1987. A. Sebben. CHUNB 03730, 03732, 03736. Although the presence of this snake in central Brazil was previously cited in Rossman (1970), these are the first vouchered records for the entire Cerrado domain. Extends range ca. 600 km N of previous record in southeastern Brazil (Rossman 1970).

Helicops leopardinus. DISTRITO FEDERAL: Brasília municipality, Gama. 20 November 1970. Collector unknown. CHUNB 03741. Extends range ca. 600 km SE of Ilha do Bananal, Tocantins (formerly Goiás); single previous record for central Brazil (Hoge 1952a).

Imantodes cenchoa. GOIÁS: São João d'Aliança municipality, Fazenda Fortaleza, 14°30'S, 47°31'W, in disturbed area close to cerrado savanna (cerrado sensu-stricto). 1 April 1997. C. Nogueira. CHUNB 20339. First state record, ca. 550 km E of the single previous vouchered record for the Cerrado, in Xavantina, Mato Grosso (Hoge 1952b).

Liophis paucidens. DISTRITO FEDERAL: Brasília municipality, SMPW, close to Núcleo Bandeirante district. May 2001. A. Bocchiglieri. CHUNB 24448. Tenth known specimen. First record for the Brasília region and sixth locality record for the taxon, all within the Cerrado domain (including Terezina, Piauí, in Cerrado/Caatinga contact, see map in Michaud and Dixon 1987). Recorded also for Emas National Park, southwestermost locality record for the taxon (Valdujo and Nogueira 2001).

Oxybelis aeneus. DISTRITO FEDERAL: Brasília municipality, Estação Ecológica de Águas Emendadas, disturbed area close to cerrado savanna (cerrado sensu-stricto). March 2001. F. França and P. H. Valdujo. CHUNB 24394. Probably the southernmost record for this wide ranging taxon, as no distribution map is available. In Brazil, this species is known only from localities in Amazonia (Keiser 1970). First vouchered record for the studied region and for the entire Cerrado.

Philodryas patagoniensis. GOIÁS: Alto Paraíso municipality, Chapada dos Veadeiros region, 14°13'S, 47°29'W, in cerrado grassland area (campo limpo). May 1986. C. Nogueira. CHUNB 19336. DISTRITO FEDERAL: Brasília municipality. 10 December 1971. Collector unknown. IB 32747. According to the distribution map in Thomas (1976), the record in the Chapada dos Veadeiros is the northernmost record for the species in Brazil. Extends range 750 km NE of single accurate record in Goiás, in Emas National Park and former northernmost record for the species (Valdujo and Nogueira 2001).

Pseudablabes agassizii. GOIÁS: São João d'Aliança municipality, Fazenda Fortaleza, 14°30'S, 47°31'W, 1050 m elev., in cerrado shrubby grassland (campo sujo). 9 April 1997. C. Nogueira. CHUNB 20357. Northernmost record for the species. First vouchered record for central Brazilian Cerrado. Extends range ca. 700 km NW of nearest known locality, Serra do Cipó National Park, Minas Gerais, southeastern Brazil (Kiefer 1998).

Rhachidelus brazili. DISTRITO FEDERAL: Brasília municipality. 16 December 1991. Collector unknown. CHUNB 03886. Northernmost record for the species, previously known only from southern and southeastern Brazil. First vouchered record for central

Brazilian Cerrado, extends range 1000 km from type locality, in the vicinity of the city of São Paulo, state of São Paulo, southeastern Brazil (Peters and Orejas-Miranda 1970).

Taeniophallus occipitalis. DISTRITO FEDERAL: Brasília municipality, Brasília National Park, in cerrado grassland (campo limpo). January 1999. C. Nogueira. CHUNB 20368. 30 February 1962. Collector unknown. IB 21447. Previously recorded from uncertain Brazilian localities (see list of examined specimens in Myers 1974). This record and the one in Emas National Park (Valdujo and Nogueira 2001) are the first for central Brazilian Cerrado.

Xenopholis undulatus. DISTRITO FEDERAL: Brasília municipality. 29 November 2000. F. França. CHUNB 20620. Although Peters (1970) mentions the presence of this taxon in the states of Goiás and Mato Grosso (no precise localities), our specimen represents the first vouchered record for central Brazil, extending range ca. 700 km NW of previously known locality records, all in Minas Gerais, southeastern Brazil, according to Peters and Orejas-Miranda (1970).

Acknowledgments.—I thank IBAMA for allowing me to collect in the studied region. The Brazilian Navy kindly allowed access to the preserved Cerrado in Área Alfa, a military training site close to Brasília where many collections were made. C. Castro-Mello and P. E. Vanzolini identified the amphisbaenians and kindly shared their knowledge on the group. F. L. Franco (IB), M. T. Rodrigues and P. E. Vanzolini (MZUSP) and G. R. Colli (CHUNB) allowed the examination of preserved specimens under their care. This work was partially funded by the CNPq (Brazilian Research Council) and FAPESP (São Paulo state research foundation), which provided fellowships.

The Apparent Persistence of *Crotalus horridus* in the Western Piedmont of North Carolina

DAVID A. STROUPE
and
MICHAEL E. DORCAS
Department of Biology, Davidson College
Davidson, North Carolina 28036, USA
e-mail (DAS): dastroupe@davidson.edu
e-mail (MED): midorcas@davidson.edu

Timber Rattlesnakes (*Crotalus horridus*) are imperiled over much of their range and efforts are underway to protect them in many states (Brown 1993). Consequently, documentation of remaining populations is vital for their conservation. In North Carolina, most extant populations of *C. horridus* occur in the mountainous (western) and coastal (eastern) regions (Palmer and Braswell 1995). Legislation is proposed that will make the snake a "Species of Special Concern" in North Carolina, affording protection from wanton killing and collection (R. Wilson and A. L. Braswell, pers. comm.).

The Piedmont of North Carolina has experienced extensive development since initial European settlement resulting in the extirpation of most *C. horridus* populations (W. H. Martin, pers. comm.). In the Western Piedmont of North Carolina, the only documented records of *C. horridus* are from Crowder's Mountain State Park in western Gaston County, Morrow Mountain State Park

in eastern Stanly County, central Union County, and an observation regarded as reliable from eastern Lincoln County (Brown 1992; Palmer and Braswell 1995). Here we document the apparent persistence of *C. horridus* in the western Piedmont of North Carolina by reporting two new county records from northern Mecklenburg County and adjacent, western Cabarrus County.

Crotalus horridus (Timber Rattlesnake). MECKLENBURG Co: Ramah Creek Conservation Easement, 3.0 km S of U.S. Rt. 73 on McAuley Road (UTM Zone 17: N3920589m, E0519984m). August 1997. Gary Sitton. NCSM 61877. Verified by Jeffrey C. Beane. New county record. The specimen was obtained by Sitton, who placed the specimen in a freezer until 28 May 2001, when we obtained it. The individual is a female measuring 1.37 m long and resembles Coastal Plain ("canebrake") forms. An additional specimen was found during June 1997 in the vicinity of the first animal (ca. 2.5 km S of U.S. Rt. 73 on McAuley Road—UTM Zone 17: N3920575m, E0519978m) in June 1997 by Margaret Zimmerman. This specimen was killed and all but its rattle discarded. The Ramah Creek Conservation Easement, where both of these specimens were found, encompasses 202 ha of undeveloped land and represents one of the largest undeveloped areas in northern Mecklenburg County. Habitat consists of mixed hardwoods and pine interspersed with a few feed plots established for deer and quail. We searched the area extensively during 2000 and 2001, and failed to find additional specimens.

CABARRUS Co: 8480 Bradford Road, Concord, North Carolina, 1.5 km N of North Carolina Rt. 73 (UTM Zone 17: N3924608m, E0526246m). 22 September 2000. Debbie Bradford. NCSM Color Slide WMP 5346. Verified by Jeffrey C. Beane. New county record. The specimen was reported in the *Concord Independent Tribune* to be between 1.3 and 1.5 m long. A second specimen was killed adjacent to North Carolina Rt. 73 on a boat ramp between LA Forest Road and Rankin Road (UTM Zone 17: N3924589m, E0526220m). July 2000. Deputy Sheriff Rick Coker. NCSM Color Slide WMP 5347. Verified by Jeffrey C. Beane. From photographs, this specimen appears to also be between 1.3 and 1.5 m long. As with the Ramah Creek specimens, these animals resemble more closely the Coastal Plain ("canebrake") form of this species. The area where these two specimens were found is comprised of a mosaic of various habitats, consisting of small farms interspersed with forested areas and stream floodplains.

Amphibians and Reptiles of the Hashemite Kingdom of Jordan. An Atlas and Field Guide, by Ahmad M. Disi, David Modry, Petr Necas, and Lina Rifai. 2001. Edition Chimaira, Frankfurt am Main. 408 pp. Hardcover. 68 DM (approx. US $30). ISBN 3-930612-12-7.

In the last few years, the quality of field guides has taken a quantum jump, thanks largely to new photographic and computer printing and publishing technologies. This has been particularly noticeable for herpetological guides for Third World countries. This guide to the herpetofauna of Jordan is an outstanding example of this new trend. The cover, which is decorated with handsome photographs, front and back, appears wear-resistant, a necessity for any field guide, and the binding seems reasonably sturdy.

As Wolfgang Böhme points out in his Preface to the book, Professor Disi is the founder of modern herpetology in Jordan. Dr. Modry and Petr Necas are Czech researchers who have spent field time in Jordan, and Lina Rifai represents the next generation of herpetologists in Jordan. This has proven a fortunate collaboration of long familiarity with the fauna with access to up-to-date literature published in the West. The photographs, which are appropriately integrated with the text are all of high quality; most are by David Modry, supplemented by a few of comparable quality by other prominent herpetologists/photographers. The printed reproduction of the photographs is of exceptionally high resolution and color rendition, and the fact that the entire book is published on paper of photographic quality has permitted the intimate association of text and illustration.

The section "Introduction and technical notes" adequately sets out the plan of the book, the purpose of which is to present current knowledge of distribution of species in Jordan and to permit the accurate identification of individual specimens. Species accounts include the current Latin names, the original name under which the species was described, along with authors' names and dates of publication. Type localities are stated. Vernacular names are given in English, German, and French; in an appendix, Arabic names are given for each species, both in Arabic script and transliterated into Roman alphabet. Subspecific designations are presented in a "Systematics" paragraph for each account. There is a "General distribution" paragraph giving the total range of the species and a "Local distribution" paragraph giving the known distribution within Jordan. A gazetteer appendix listing all localities mentioned in the text is particularly valuable. For each species account there are paragraphs for "Habitat," "Description," "Notes on biology," and "Remarks." Because this is a field guide, rather than a scientific

treatise, researchers will be greatly aided by the "Pertinent literature" at the end of each account, which refers the reader to the bibliography containing the technical literature available for the species. Each species account typically includes at least two color photographs of the animal, one showing the entire animal, another a close-up of the head showing details of scalation and color pattern. Sometimes both male and female are illustrated.

The distribution maps for each species merit special mention. The authors have overlain an outline map of Jordan with a grid of squares, 15 minutes on each side. Each square in which a particular species has been recorded is occupied by a solid black dot. Although this may not be as precise as individual locality symbols, it is particularly appropriate in a field guide that can also be used in comparing distribution patterns and in making inter-area faunal comparisons. In their introduction, the authors present a map summarizing all of the squares in which any species have been recorded. It is immediately apparent that a bit less than half of the area of the country remains unexplored herpetologically. It is reasonable to assume that few or none of the occupied squares have been thoroughly canvassed.

Following the Introduction, the book begins with a brief chapter on the geography and climate of Jordan. The authors recognize four general physiographic regions: the Rift Valley, Mountain ranges along the eastern flank of the Rift, the Eastern Desert, and the marine environment of the Gulf of Aqabah. This chapter includes habitat photos and maps showing prominent physiographic features and temperature and rainfall distribution. The two-page chapter on biogeography attempts to give a brief descriptive overview of the ecological occurrence of the herpetofauna. The authors recognize four "ecozones," the Mediterranean ecozone, Irano-Turanian ecozone, Saharo-Arabian ecozone, and the Afrotropical (or Sudanian) ecozone. They list characterizing vegetation and representative species of amphibians and reptiles for each of these regions. A brief chapter covers the history of herpetological research in Jordan. Suggestions for the observation and collecting of amphibians and reptiles form a chapter, and a chapter on conservation includes descriptions of the protected areas in Jordan. Reptiles and amphibians in the cultural heritage of Jordan constitute a short chapter, in which some account of folklore is presented, along with a Bedouin recipe for cooking and serving *Uromastyx aegyptius*.

A longer chapter on venomous snakes and snakebite is well illustrated with photographs of the venom apparatus of the principal venomous snakes, some account of snake venoms, and brief accounts of each of the venomous species: *Cerastes gasperettii, Pseudocerastes persicus, Echis coloratus, Vipera palaestinae, Macrovipera lebetina, Atractaspis engaddensis*, and *Walterinnesia aegyptia*. Symptoms and treatment of snakebite along with folk medicine and practices are covered in this chapter.

Following these general chapters, which occupy 74 pages, are the keys to amphibians and reptiles of Jordan. Key characters are illustrated primarily with photographs rather than with the more traditional line drawings (with a few exceptions, such as line drawings of the heads of lizards and snakes and turtle shells, where the names of scales and plates appear). Interestingly, in the case of amphibians, only a single species in each of five families occurs in Jordan, and so family keys to both adults and larvae suffice. The dichotomous keys to the reptiles appear to be quite workable for specimens in the hand. Field identification of living amphibians and reptiles will be possible in most cases through examination of the photographs in the species accounts.

The authors list 89 species, 4 frogs, 45 lizards, 34 snakes, and 6 turtles for Jordan, with another 9 species of possible occurrence or doubtful status. Each species is beautifully illustrated with color photographs of the living animals, and each account has a distribution map. The nomenclature used is current, and the pertinent literature section for each account is sufficient to track down nomenclatural history in most cases. I have no argument with the specific usage here, although for each taxon there are those more expert than I, and I leave such criticism to them. The up-to-publication-date bibliography is extensive and appears to be complete for those references pertaining strictly to Jordanian herpetology and to adjacent regions as appropriate.

It seems to be a tradition of reviewers to find fault, however minor, with some aspect of a publication, in order to be "helpful" in future revisions. As none of the authors is a native speaker of English, the language will seem not quite idiomatic to many readers, although the meaning is clear. There is no index, a minor inconvenience, since the table of contents and the arrangement of species accounts will quickly lead the reader to the desired information.

This book will be a necessary and welcome addition to the library of all zoologists working on the fauna of Southwest Asia and to any museum collection that includes herpetological material from the region. It will be a valuable field tool to those with conservation management responsibilities in Jordan and for zoology courses in Jordanian universities. One may hope that there will be an Arabic version, also. The book will also be of interest to anyone looking for a model for state-of-the-art field guides. It would be a blessing if it were the prototype for a series of field guides to the various zoological taxa of the region.

As with all areas of Asia, systematic and natural history studies are far from complete, and I would expect that there will be future revised editions of this guide. It is fortunate, if ironic, that we have entered an age of beautifully executed field guides just as studies of morphological and adaptive characters are falling out of favor, and natural history studies are seen as beneath the dignity of "real" scientists. One wonders if there will be future generations trained to make the necessary emendations to current field guides, so necessary to the conservation of biological diversity.

Amphibians of Argentina: A Second Update, 1987–2000, by Esteban O. Lavilla and José M. Cei. 2001. Monographie XXVII, Museo Regionale di Scienze Naturali Torino, Via Giolitt 36, 10123 Torino, Italy. Hardcover. 35,000 Lira (about US $18). ISBN 88-86041-41-1.

WILLIAM E. DUELLMAN
Natural History Museum and Biodiversity Research Center
The University of Kansas, Lawrence, Kansas 66045, USA
e-mail: duellman@ku.edu

The amphibian fauna of Argentina was documented comprehensively by the indefatigable field naturalist and herpetologist José M. Cei in 1980; therein he provided keys,

accounts of all of the genera and species, distribution maps, many line drawings of tadpoles and structures of adults, and 24 plates that are composites of color paintings by the late Sylvana S. Cei. This outstanding work initiated a new phase of herpetological research in Argentina by scores of young investigators. Cei also continued an active field program in Argentina and in 1987 published a lengthy update to his earlier monograph.

One of the young investigators inspired by Cei is Esteban O. Lavilla, who has collaborated with Cei to bring us a new update of the amphibians of Argentina. This new volume of 177 pages contains updated accounts of all of the genera and species and 24 very good color photos of living individuals, mostly of species previously not illustrated in color; these are grouped on eight plates at the end of the volume. Comments on conservation status are included in the accounts of some species. An appendix of 11 pages contains transcriptions of original descriptions of Argentinean anurans published in 1987–1997, and a second appendix of 19 pages is an addendum to the main text in that it contains a review of the literature published in late 1997 through mid-2000.

Essentially, the species accounts are updates from the previously published works. Thus, for some species the account consists of nothing more than "No additional data reported since 1987." Most accounts, are more lengthy and include information on taxonomy, distribution, life history, or descriptions of larvae. Nearly all of the information has been synthesized from the literature, much of which has been published in Argentina. The literature cited is fragmented in that references appear at the end of the accounts of individual genera. The work is indexed thoroughly.

The quality of the paper and binding is excellent, as is characteristic of the monographs of the museum in Torino. In general, the writing is clear and concise, but the manuscript would have benefited by careful editing by a person whose native language is English.

In the two decades since the original work was published, the known amphibian fauna of Argentina has increased significantly—from two genera and two species of caecilians and 31 genera and 119 species of anurans to three genera and four species of caecilians and 36 genera and 155 species of anurans. By comparison with the tropical countries to the north, the amphibians fauna is proportionately small in Argentina, inasmuch as the Patagonian and Pampas-Monte regions of the country are semiarid. However, a significant part of the anuran fauna is endemic to Patagonian Argentina or to the austral forests of southern Argentina and adjacent Chile.

This publication provides an entrée to the recent literature on Argentinean amphibians and is an important update to the previous works by Cei. As such, it is an indispensable book for anyone interested in the amphibian fauna of austral South America.

PUBLICATIONS RECEIVED

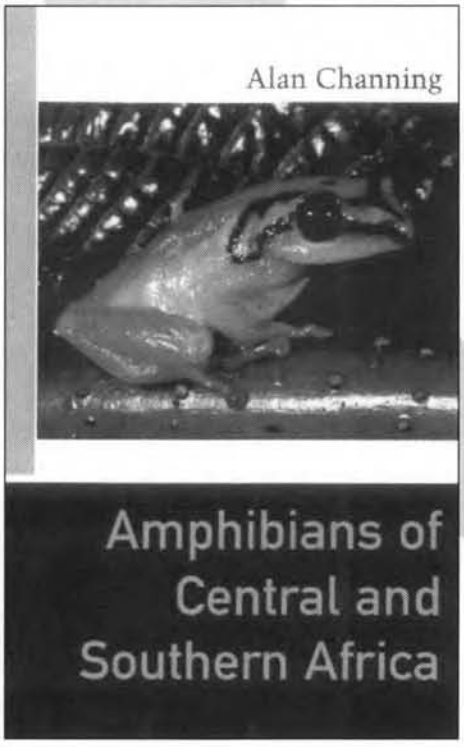
El Camaleón en Andalucía. Distribución Actual y Amenazas para su Supervivencia, by Jesús Mellado, Lola Giménez, Juan J. Gómez, and Marieta Sanjuán. 2001. Fundación Alcalde Zoilo Ruiz-Mateos. Rota, Cádiz, Spain [orders to Juan Pedro Caballero, Fundación Alcalde Zoilo Ruiz-Mateos, c) Charco, 15, Rota E-11520 Cádiz, Spain; fax: 34 956 813450). 147 pp. Softcover. 2500 pts or 15.02 Euro (approx. US $13.50) + postage and packing. ISBN 8487960-31-6.

This large format (30 x 21 cm) book provides a current overview of the common chameleon in Andalusia, southern Spain. Included is information about ecology, distribution, population density and conservation. The book includes 21 geo-referenced maps, 20 tables, 40 text figures, and 7 color plates. It presents a fine-scale analysis based on a seven-year study (1993–1999). Threats to the remaining populations are identified and evaluated including road deaths, translocations, and, most importantly, habitat modification and destruction. The authors propose a new conservation status for the chameleon in Spain and make suggestions for its management and future conservation.

Die Schildkröten des Indischen Subkontinents, by Indraneil Das. 2001. Edition Chimira, Frankfurt am Main. 181 pp. Hardcover. 68 DM (approx. US $30). ISBN 3-930612-35-6.

This book is a German translation of the 1995 book *Turtles and Tortoises of India* by Das (not to be confused with the 1991 book *Colour Guide to the Turtles and Tortoises of the Indian Subcontinent* by the same author). The bulk of the book is devoted to species accounts for each living chelonian in the Indian region (including India, Pakistan, Sri Lanka, Bangladesh, Nepal, Bhutan, and Maldives). There is also a short section covering fossil turtles of the region, an illustrated key to species, a glossary, and index. The translation by Thomas Wilms is accurate, but not exact. Some sections have been shortened and others have been augmented by new information. In addition, the book includes shaded distribution maps (not present in the original) and many new photographs. Recent taxonomic changes have been incorporated and the bibliography has been updated with numerous references that have appeared since 1995. The sturdy hardcover is an improvement over the softbound original as is the quality of photographic reproduction. An entirely new section (pp. 10–18) on the captive care of Indian turtles has also been added. The numerous updates make this volume substantially different than its parent English language edition and will provide German language readers with a concise and current guide to the turtles of South Asia.

Amphibians and Reptiles of Pennsylvania and the Northeast



Arthur C. Hulse, C. J. McCoy and Ellen Censky

Until now, no detailed treatment of the Pennsylvania herpetofauna has ever been published, nor have recent books dealt with the herpetofauna of the entire northeastern United States. *Amphibians and Reptiles of Pennsylvania and the Northeast* is a comprehensive guide to the amphibians and reptiles of the whole region.

Amphibians and Reptiles of Pennsylvania and the Northeast:

- contains complete and easy-to-use keys to all the reptiles and both the adult and larval amphibians of the Northeast.
- features high-quality photographs to illustrate all species of amphibians and reptiles in the region as well as their significant color variations and life history stages.
- includes detailed spot-distribution maps of each species within Pennsylvania and outline maps of each species' distribution throughout the northeastern United States.
- presents extensive new data on the status and distribution of the amphibians and reptiles of Pennsylvania.

Comstock Books in Herpetology, Aaron M. Bauer, Consulting Editor
32-page color insert, 42 line drawings, 83 maps, 57 tables $39.95

Amphibians of Central and Southern Africa

Alan Channing

Amphibians of Central and Southern Africa is the first comprehensive guide to the frogs, toads, and caecilians of the ten sub-equatorial African countries—Angola, Botswana, Lesotho, Malawi, Mozambique, Namibia, South Africa, Swaziland, Zambia, and Zimbabwe. The result is at once a valuable reference tool, a field guide, and a source of ideas for future research.

Key features of *Amphibians of Central and Southern Africa* include:

- detailed accounts for 205 species of frogs and toads (and 2 species of caecilian) accompanied by color illustrations, distribution maps, details of breeding and tadpole behavior, and call descriptions.
- illustrations and tadpole identification keys for each genus.
- special sections for some species with topics such as "skin toxins".
- an overview of fossil frogs, a discussion of humankind and frogs in Africa, and a bibliography of African frog biology.

The Cuban Treefrog in Florida

Life History of a Successful Colonizing Species

Walter E. Meshaka, Jr.

"A wonderfully detailed account of an alien species in the U.S. . . . The author provides intriguing details of the natural history of the Cuban Treefrog in Florida and why it has been so successful in its new home."—Robert W. Henderson, curator of herpetology, Milwaukee Public Museum

In one of the most detailed accounts of the ecology of an introduced species in the United States, Walter Meshaka presents the natural history of the Cuban Treefrog from the perspective of its phenomenal success, in terms of sheer numbers and geographic range, as a colonizer in South Florida and the Everglades.

83 figures, 71 tables.Cloth, $69.95

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, and Legislation & Conservation should be sent directly to the appropriate section editor. Send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, Herpetological History, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without consulting the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the Editor or Managing Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://www.ukans.edu/~ssar/HRadRates.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, Saint Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, Saint Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the Editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 740		US $440
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 740	$300

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

mating period is shorter (about 24 h). Throughout the mating period the pair stay in close contact. Eggs are buried in the substrate, usually at night (despite the 24 h light cycle). They are removed immediately and incubated in a 1:1 mixture by weight of perlite and water. Initially clutches were incubated at a constant 30.6°C. Under these conditions eggs of all species hatched after 90–100 days (exceptionally 65–110 days). Subsequently, incubation temperatures were allowed to fluctuate between 28.5°C and 32.5°C. Incubation times for individual species under these conditions are given below.

Varanus kingorum has been maintained since 1993. During this time six generations of captive animals have been produced. Clutch size is typically two but as many as six eggs have been laid. Up to 14 clutches of eggs have been produced by a single female in as many months. Incubation takes 65–80 days under the conditions described above. Hatchlings have a total length of about 15 cm. Both sexes become sexually mature at four months of age. Males are removed from enclosures after egg laying to allow females to regain condition.

Since 1996 *V. glauerti* have produced a total of five generations of captive bred animals. Females produce up to 68 fertile eggs in eight clutches over eight months; eggs hatch after 90–110 days. Average clutch size is nine with a maximum of 12 eggs. Hatchlings measure approximately 18 cm total length and can reach maturity at around seven months of age. Males are separated from females after egg laying.

Since 1997 three generations of *V. pilbarensis* have been produced. Clutch size averages four eggs, with a maximum of six. Up to six clutches are produced per year, usually laid two weeks apart over 2–3 months followed by a pause of nine months. Eggs typically hatch after 80 days, sometimes as quickly as 65 days. Hatchlings measure approximately 13 cm total length and can reach sexual maturity as early as eight months of age. It has not been necessary to separate sexes after egg laying because females regain condition rapidly.

Three generations of *V. caudolineatus* have been produced since 1997. Typically 5–6 clutches of eggs are produced over four months, followed by an eight month pause. Clutch sizes of 2–3 eggs are common, however a maximum of five eggs have been laid. The eggs hatch between 65 and 80 days and reach sexual maturity at the age of five months. It has not been necessary to separate sexes after egg laying.

Although multiple clutches have been recorded many times in captive monitor lizards (Card 1994; Horn and Visser 1990, 1997; Vincent and Wilson 1999) and occasionally in wild populations (Shine et al. 1996), the numbers of clutches reported here are much higher than those previously reported for any captive monitor lizard. Similarly, the ages at maturity reported here are much lower than those in the literature. The results suggest that, given conditions of almost unlimited access to food and heat, these lizards are capable of much higher rates of growth and reproduction than had been previously supposed. They further suggest a capacity for rates of metabolism that are at present undocumented.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 32, Number 1 (March 2001). Submissions should be directed to one of the section editors (contact information located on inside front cover of this issue), as follows: amphibians (Painter); lizards, amphisbaenians, crocodilians, *Sphenodon* (Hayes); snakes and turtles (Butterfield).

CAUDATA

BATRACHOSEPS STEBBINSI (Tehachapi Slender Salamander). **ATTEMPTED PREDATION.** Examples of predation are known for only a few species of *Batrachoseps*, and none has been reported for *B. stebbinsi*, a species with a very restricted distribution in the Tehachapi Mountains of south-central California, USA (Hansen and Wake, *in press*. *In* M. J. Lannoo [ed.], Status and Conservation of U.S. Amphibians. University of California Press, Berkeley).

On 18 March 2000, two of us (TB, SW) observed a female *Diadophis punctatus* (190 mm SVL) attempting to constrict an adult *B. stebbinsi* (54 mm SVL). Both were located beneath small rocks at the base of a north-facing talus slope. The snake had seized the salamander just anterior to the hind limbs and was attempting to encircle the salamander's body with coils, but with little success. The snake appeared rather thin, perhaps having recently emerged from winter dormancy. After a ca. 15 minute struggle, the salamander dislodged the snake by dragging it down among smaller rock fragments and escaped. This observation was made at 1400 h at an air temperature of 20°C within Caliente Canyon, Kern County, California.

Ringneck snakes readily consume *Batrachoseps* in captivity (Hubbard 1903. Univ. California Publ. Zool. 1:157–170; RWH, pers. obs.). As the distribution of *D. punctatus* overlaps the ranges of most species of *Batrachoseps*, several authors (e.g., Stebbins 1954. Univ. California Publ. Zool. 54:47–124) have suggested that ringneck snakes likely are natural predators.

Submitted by **TIMOTHY BURKHARDT** and **SAMANTHA WINEGARNER**, 49 Blossom Drive, San Rafael, California 94901, USA (e-mail: TriprionCO@aol.com) and **ROBERT W. HANSEN**, 16333 Deer Path Lane, Clovis, California 93611-9735, USA (e-mail: rwh13@csufresno.edu).

EURYCEA LONGICAUDA LONGICAUDA (Long-Tailed Salamander). **PREDATION**. Little is known about predation pressures faced by long-tailed salamanders. On 17 Sept 2000, we col-

lected an adult *Pseudotriton ruber ruber* (62 mm SVL) during a field survey in Wayne County, Ohio, USA. The *P. ruber* was found under a small sandstone slab on a hillside adjacent to a small spring-fed stream. The salamander was brought back to the laboratory, anestisized in a 0.2% chloretone solution, and preserved in 10% formalin. While in the anesthesia the *P. ruber* regurgitated an adult *Eurycea longicauda*. Although the body was partially digested, the body just anterior to the rear legs to a point midway down the tail was intact allowing for a positive identification. *Pseudotriton ruber* are opportunistic foragers known to prey on invertebrates and other species of salamanders. A literature review of salamander predation by *P. ruber* found that two Ohio juveniles had each consumed *Plethodon cinereus* (Bock and Fauth 1992. Herpetol. Rev. 23:58) and a specimen from New York had also consumed *P. cinereus* (Bishop 1941. Salamanders of New York. New York State Mus. Bull. 324:1–365). This is the first report of predation on *E. longicauda* by *P. ruber* of which we are aware.

Female *E. longicauda* move to breeding sites in seepages or streams in the late autumn (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press. 587 pp.). *Pseudotriton ruber* also congregate near springs during the late fall (Bishop. 1941, *op.cit.*). Given the considerable overlap in the ranges of the two species in eastern North America, and their similar habitat selection during the fall season, adult *P. ruber* may be one of the major predators of *E. longicauda* at these spring localities.

This project was funded by the Wildlife Diversity and Endangered Species Program of the Ohio Division of Wildlife and managed by the Ohio Biological Survey. The *P. ruber* and the regurgitated *E. longicauda* were deposited at the Cleveland Museum of Natural History (catalog number 8817).

Submitted by **JARET S. REBLIN** and **CARL D. ANTHONY**, Department of Biology, John Carroll University, University Heights, Ohio 44118, USA.

PLETHODON CINEREUS (Red-backed Salamander). **SITE ATTACHMENT.** *Plethodon cinereus* is commonly found under logs, leaf litter, and rocks (Harding 1997. Amphibians and Reptiles of the Great Lakes Region. Univ. Michigan Press, Ann Arbor. 378 pp.) in late-successional deciduous forests of northeastern North America (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.). *Plethodon cinereus* are most active at night, when they leave their cover objects to forage on the forest floor (Adler 1969. Science 164:1290–1291; Adler 1970. J. Herpetol. 4:99–112). Upon completion of their nocturnal wanderings, *P. cinereus* have been found to regularly return to the same cover objects (Gergits and Jaeger 1990. J. Herpetol. 24:91–92), which indicates site attachment. Further evidence for the occurrence of site attachment in *P. cinereus* was provided by Placyk (2000. Sensory Mediation of Foraging Behavior in *Plethodon cinereus*, the Redback Salamander. M.S. Thesis, Northern Michigan University. 72 pp.), who recaptured 78% of 50 *P. cinereus* from the same home sites that they had originally been collected from one month prior to recapture. It is possible that this site attachment by *P. cinereus* may occur across seasons, but there are no data to support such a hypothesis.

On 10 August 1998, while hiking along the Little Garlic River in Marquette, Marquette County, Michigan, USA, one of us (JSP) encountered an adult *P. cinereus* with a missing tail, under a log adjacent to the hiking trail. The animal was toe-clipped for future identification and placed back under the same log. On 3 September 1999 the same *P. cinereus* was rediscovered by JSP under the same log. The salamander was identified by the presence of the correct toe-clipping code and a freshly regenerated tail. After identifying the salamander, it was placed under the same log. This is the first observation of long-term site attachment in *P. cinereus* and provides support for the hypothesis that *P. cinereus* maintain the same home site across seasons. This observation warrants more detailed studies that fully explore the occurrence and function of long-term site attachment in this species.

Submitted by **JOHN S. PLACYK, JR.**, Department of Ecology and Evolutionary Biology, 569 Dabney Hall, University of Tennessee, Knoxville, Tennessee 37996-1610, USA (e-mail: jplacyk@utk.edu), and **BRENT M. GRAVES**, Department of Biology, Northern Michigan University, Marquette, Michigan 49855, USA.

PLETHODON JORDANI (Jordan's Salamander). **VOCALIZATION.** Several species of North American salamanders are known to vocalize, including species within the families Ambystomatidae (*Ambystoma gracile*, *A. maculatum*, and *A. texanum*), Plethodontidae (*Ensatina eschscholtzi, Aneides lugubris*, and *Plethodon glutinosus*), Dicamptodontidae (*Dicamptodon ensatus*), and Salamandridae (*Taricha torosa*) (Brodie 1978. Copeia 1978:127–129; Brodie et al. 1979. Copeia 1979:270–274; Davis and Brattstrom 1975. Herpetologica 31:409–412; Neill 1952. Copeia 1952:195–196; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington. 587 pp.; Wyman and Thrall 1978. Herpetologica 28:210–212). Each of these species uses vocalizations as a component of defensive displays, but vocalizations may have other functions as well (Wyman and Thrall, *op. cit.*). Although its defensive behavior has been studied in the laboratory, vocalizations by *Plethodon jordani* have not been reported (Brodie et al., *op.cit.*). In this note we report the observation of vocalization in two adult *P. jordani*.

On 25 July 2000 at ca. 1115 h, two adult *P. jordani* were captured during an amphibian survey in Great Smoky Mountains National Park (GSMNP), North Carolina, USA. Both salamanders were gray-cheeked individuals and had white flecking along their sides, indicating that these individuals may be members of the recently elevated taxon *P. metcalfi* (*sensu* Highton and Peabody 2000. In Bruce et al. [eds.], The Biology of Plethodontid Salamanders, pp. 31–93. Kluwer Academic/Plenum Publishers, New York), or possible hybrids of *P. jordani* and *P. oconaluftee* (Petranka, *op. cit.*). Both salamanders were found beneath cover objects along Beech Gap Trail (Luftee Knob Quadrangle, 33°38'05"N, 83°12'20"W) at an elevation of ca. 1267 m. At the time of the observation the air temperature was 18.8°C and the relative humidity was 71%. Skies were partly cloudy.

When captured, each of the two individuals responded with the same behavior. While held in the hand, the salamanders produced a faint chirping and slapping sound that appeared to be produced by a combination of thoracic muscle contraction and mouth movements. The slapping sound appeared to be produced by the mouth opening and closing. It is unclear, however, what the origin of the

chirping noise was and whether the thoracic contraction played a role in sound production. Both sounds were produced simultaneously and only a few times by each salamander. When released, both individuals discontinued the vocalization behavior.

Although vocalization has not previously been reported in *P. jordani*, this species is known to produce noxious tail secretions and engage in tail displays (Brodie et al., *op. cit.*). It is possible, therefore, that vocalizations are one component of an aposematic display that also includes visual displays involving the tail and the bold coloration seen in many populations of *P. jordani*. However, since the taxonomic status of these individuals from GSMNP is uncertain (i.e., whether they represent *P. jordani, P. metcalfi*, or *P. jordani* x *oconaluftee*) and both individuals came from the same population and locale, it cannot be concluded that this behavior is typical of *P. jordani*. Future studies of defensive behavior of *P. jordani, P. metcalfi, P. oconaluftee*, and their respective hybrids may clarify the phylogenetic origin of the behavior reported here.

These observations were made in conjunction with the USGS Southeastern Amphibian Research and Monitoring Initiative under permits from Great Smoky Mountains National Park (GRSM 00-025) and the North Carolina Wildlife Resources Commission (No. 0100). We are grateful for suggestions and advice from C. Kenneth Dodd, Jr. and Lora L. Smith.

Submitted by **KEVIN G. SMITH** and **WILLIAM J. BARICHIVICH**, U.S. Geological Survey, Florida Caribbean Science Center, 7920 NW 71st Street, Gainesville, Florida 32653, USA.

ANURA

ATELOPUS TRICOLOR (Three-colored Stubfoot Toad). **NOCTURNAL CALLING**. Anurans belonging to the neotropical bufonid genus *Atelopus* are regarded as primarily diurnal animals (Lotters 1996. M. Vences & F. Glaw Verlags GbR, Koln.143 pp). Reduced ear structures, as well as the preferred habitat of swiftly flowing streams (McDiarmid 1971. Bull. Los Angeles Co. Mus. Nat. Hist. Sci. 12:1–66), have led previous authors to investigate the role of visual communication in this genus (Crump 1988. Anim. Behav. 36: 1064–1077; Jaslow 1979. J. Herpetol. 13:141–145; Peters 1973. Smithson. Contr. Zool. 145:1–49). Auditory signals and reception of sound in *Atelopus* have been looked at in less depth (Jaslow and Lombard 1996. Copeia 1996:428–432; Lindquist and Hetherington 1996. J. Herpetol. 30:347–354), but have noted the importance of vocalization in the genus.

Atelopus tricolor (Boulenger 1902; Lötters and De la Riva 1998) is dark brown with two yellow dorsolateral stripes, a yellow venter spotted with brown, and vividly contrasting vermilion palms, soles, and vent. This coloration is consistent with the visual communication systems described in other species (Crump 1988, *op. cit.*; Lötters 1996, *op.cit.*). During herpetological surveys conducted along the Paucartambo-Pilcopata road, Departamento Cuzco, Peru, *A. tricolor* were most frequently found sleeping on streamside vegetation less than 1 m in height.

On the night of 12 Jan 2000, a chorus of male *A. tricolor* was located at the base of a small cascade within primary cloud forest at 1525 m elev. The stream is a tributary of Union Creek, a larger body of water in which the rheophilic tadpoles of *A. tricolor* were found. Eight individuals occupied conspicuous positions on boulders protruding from the pool of water at the base of the cascade, and continued to call for more than two hours. Other anuran species calling in the area included *Hyla phyllognatha, H. balzani*, and *Cochranella trubae*. The chorus was relocated and observed on 13 and 14 Jan 2000.

Previous authors have theorized a correlation between reduction of vocal communication and increased visual signaling in areas of high background noise (Lindquist and Hetherington 1996, *op. cit.*). It is unusual that we documented a diurnal, aposematic toad calling nocturnally at the base of a waterfall.

We thank Manu Nature Tours, The Evergreen Foundation, and The Naturalist Network for their continued support of the Reptiles and Amphibians of Manu project.

BUFO OCCIDENTALIS (Pine Toad). **DEATH FEIGNING.** Little is known about the natural history of the endemic Mexican toad *Bufo occidentalis* (Oliver-López et al. 2000. Herpetol. Rev. 31:39–40). Herein we describe a possible antipredator behavior of *B. occidentalis*.

At 2034 h on 29 Sept 2000 at "El Charcote" ca. 6 km SW of Zapotitlán Salinas (18°20'N, 97°26'W; 1600 m elev.), Puebla, México, we collected a juvenile male *B. occidentalis* (KAB 031; 40 mm SUL) hidden in an algal mat in a small pond ca. 2.4 m deep. Upon capture the specimen became immobile with its limbs rigid, and breathing was not apparent for 4.5 minutes. When the rigid limbs were stretched and released, they were withdrawn tightly against the body. The toad was then placed on the ground where it remained in a belly-up position until it righted itself ca. 2.5 min later. Another juvenile male (KAB 039; 58.6 mm SUL) collected from near the same area at Rio Salado ca. 8 km N of "El Charcote," assumed the same behavior for a shorter time (90 sec). Other juveniles collected that were <60 mm SUL exhibited this same death-feigning behavior, however 14 males and 3 females >60 mm SUL did not.

LIMNODYNASTES TASMANIENSIS (Spotted Grass Frog) and ***LITORIA LESUEURI*** (Leseur's Frog). **ENDOPARASITES.** *Limnodynastes tasmaniensis* (Myobatrachidae) is widely distributed throughout Australia: Tasmania, Victoria, eastern South Australia, New South Wales and eastern Queensland. *Litoria lesueuri* (Hylidae) occurs in eastern Australia from northern Queensland to Victoria (Cogger 2000. Reptiles and Amphibians of Australia. 6th ed. Ralph Curtis Books. Sanibel Island, Florida. 808 pp.). Barton (1994. Rec. S. Aust. Mus. 27:13–30) published a checklist of helminth parasites of Australian Amphibia. The purpose of this note is to add new helminth host records for *L. tasmaniensis* and *L. lesueuri* to that list. Twenty frogs from the herpetology collection of the Natural History Museum of Los Angeles County, Los Angeles (LACM) were examined: ten *L. tasmaniensis,* five from Victoria (LACM 41469, 41471–41474), five from New South Wales (LACM 41475, 41476, 41478, 41480, 41481) and ten *L. lesueuri* (LACM 41287–41296) from Victoria. The body cavity was opened with a mid-ventral incision. The lungs, urinary bladder and digestive tract were removed for helminthological examination. The body cavity was also examined for helminths. Nematodes were removed, cleared in a drop of concentrated glycerol and identified under a compound microscope. Two species of nematodes were found in *L. tasmaniensis* from Victoria: *Oswaldocruzia limnodynastes* and *Parathelandros limnodynastes;* two species of nematodes in *L. tasmaniensis* from New South Wales: *Parathelandros limnodynastes* and *Rhabdias hylae;* and two species of nematodes in *L. lesueuri* from Victoria: *P. limnodynastes* and *R. hylae.* Voucher specimens of these helminths were deposited in the United States National Parasite Collection, Beltsville, Maryland, (USNPC): *L. tasmaniensis*, *O. limnodynastes* (USNPC 91188), *P. limnodynastes* (USNPC 91189), *R. hylae* (USNPC 91190); *L. lesueuri, P. limnodynastes* (USNPC 91191), *R. hylae* (USNPC 91192). Prevalence of infection (number frogs infected/number frogs examined x100) and mean intensity (mean number of nematodes per infected frog ± 1 SD) and range by helminth species for *Limnodynastes tasmaniensis* was *O. limnodynastes* 10%, 2.0, (1 infected frog), *P. limnodynastes* 50%, 3.4 ± 2.9, 1–8; *R. hylae* 30%, 2.0 ± 1.0, 1–3, respectively; prevalence, mean intensity and range by helminth species for *Litoria lesueuri* was *P. limnodynastes* 50%, 8.2 ± 8.7, 1–23; *R. hylae* 10%, 1.0 (1 infected frog), respectively.

Oswaldocruzia limnodynastes is known from *Limnodynastes dorsalis* from South Australia, *Litoria aurea* from New South Wales and *Litoria peronii* from South Australia; *Parathelandros limnodynastes* in *Limnodynastes dorsalis* from South Australia; and *Rhabdias hylae* from 22 species of anurans across Australia (Barton, *op. cit.*). *Limnodynastes tasmaniensis* represents a new host record for *O. limnodynastes* and *P. limnodynastes*. *Litoria lesueuri* represents a new host record for *P. limnodynastes*.

We thank David A. Kizirian (LACM) for permission to examine *L. tasmaniensis* and *L. lesueuri.*

PSEUDACRIS STRECKERI ILLINOENSIS (Illinois Chorus Frog). **DYSFUNCTIONAL VOCAL SAC.** On 15 Feb 2001 at ca. 2130 h we visited a breeding chorus of *Pseudacris streckeri illinoensis* in the vicinity of Nimmons, Clay County, Arkansas, USA. A male was observed by BAW with his vocal sac protruding out of the water causing him to float at the surface, and unable to submerge. The frog was collected and returned to the Arkansas State University Herpetology Museum for observation. The vocal sac remained inflated through 1 March 2001. This anomaly is interesting as individuals would be highly susceptible to predation and their reproductive potential is likely reduced. This male appeared incapable of calling to attract mates. It is also unlikely this frog could grasp a female because the frog floated with the body hung below the surface while the vocal sac floated on the water's surface. The specimen usually was observed on its back, unable to right itself until the vocal sac deflated. The specimen is being held alive at the museum for return to the collection site or later depo-

sition in the ASU herpetological collection.

GYMNOPHIONA

ICHTHYOPHIS KOHTAOENSIS (Kho-Tao Caecilian). **MAXIMUM LENGTH**. Taylor (1969. Univ. Kansas Sci. Bull. 48:297–305) gave a total length of 330 mm for an adult *Ichthyophis kohtaoensis*. He classified the caecilian as a rather large ichthyophiid (Taylor 1968. The Caecilians of the World. Univ. Kansas Press, Lawrence. 845 pp.). We found two gravid females reaching a total length of almost 400 mm. The first female (TL 398 mm; 60.5 g) was captured on 23 January 2000 near the city of Khemerat (Province Ubon Ratchathani, Northeastern Thailand, 16°5'N, 105°15'W). It was excavated from the soil near a small brook (depth 12 cm, soil temp 21°C). The second specimen (TL 396; 57.2 g) was found on 23 September 2000 on a road near a suburb of Hat Yai (Province Songkhla, Southern Thailand, 6°55'N, 100°15'W).

TESTUDINES

CARETTA CARETTA (Loggerhead Sea Turtle). **ABNORMAL NESTING BEHAVIOR**. Loggerhead sea turtles have very stereotypical nesting behaviors (Hailman and Elowson 1992. Herpetologica 48:1–30). After a female has dug the nest chamber, she lays her eggs, fills the chamber with sand, camouflages the nest, and returns to sea. Herein we report unusual nesting behavior observed in two loggerheads nesting on Busca Vida Beach, Bahia, Brazil. These turtles dug an egg chamber and commenced ovipositing, then started covering the eggs with sand only to stop and recommence ovipositing. This procedure was repeated ca. five times by one female and ca. nine times by the other female. The straight carapace lengths (= distance from middle of nuchal to pygal tip) of the loggerheads were 95.3 cm and 90.1 cm. The larger female laid a clutch of ca. 145 eggs including one unusually large egg, which was broken by her hind flippers, and an abnormal L-shaped egg that measured ca. 14.6 cm in length. The smaller turtle laid ca. 127 eggs, two of which were joined together. Fourteen broken eggs were found in the larger clutch, and one broken egg was found in the smaller clutch. The females broke the eggs with their flippers. No data on hatching success are available.

Some chelonians such as the map turtle, *Graptemys geographica*, separate egg layers with thin layers of mud (Ernst and Barbour 1972. Turtles of the United States. University of Kentucky Press, Lexington, Kentucky. 347 pp.; Ehrenfeld 1979. *In* Harless and Morlock [eds.], Turtles: Perspectives and Research, pp.417–434. Wiley and Sons, New York), but this behavior has been recorded only once for sea turtles (Caldwell 1962. Quart. J. Florida Acad. Sci. 25:287–302). Caldwell (*op. cit.*) recorded similar behavior in two loggerheads on Jekyll Island, Georgia, but these turtles only separated two layers of eggs by one layer of sand. Caldwell (*op. cit.*) hypothesized that these animals were young, inexperienced nesters because of their small body sizes, small clutches, early nesting, and unusual behavior. However, the body size and clutch size of the larger female we observed do not support this hypothesis. The mean carapace length reported for the Brazilian loggerhead population is 92.9 cm and the mean clutch size is 130.5 eggs (Tiwari and Bjorndal 2000. Herpetologica 56:343–356). Additionally, the smaller female had been observed to produce a normal nest two weeks prior to this event.

Shifts among the phases of the nesting sequence may result from external stimuli (Hailman and Elowson, *op. cit.*). For instance, the shift from digging the egg chamber to ovipositing is apparently triggered when the hind flippers come up without sand on at least two consecutive digging attempts. Termination of oviposition may be controlled by an external stimulus when the cloacal tip touches the egg pile, or by an internal stimulus, possibly depletion of eggs (Hailman and Elowson, *op. cit.*). It is difficult to ascertain what triggered the aberrant behavior we observed.

Submitted by **MANJULA TIWARI**, Archie Carr Center for Sea Turtle Research, University of Florida, P.O. Box 118525, Gainesville, Florida 32611, USA, and **ALEX SILVEIRA**, Fundação Pró-Tamar, Caixa Postal 2219, Salvador, Bahia, CEP 40210-970, Brazil.

CHELONIA MYDAS* and *CARETTA CARETTA (Green Turtle and Loggerhead Turtle). **OUT-OF-SEASON TAG RETURNS**. During the early and mid-1980s a number of hatchling sea turtles were head-started as part of a sea turtle project operated by The Conservancy of Southwest Florida. The hatchlings released as a result of this program included both green (*Chelonia mydas*) and loggerhead (*Caretta caretta*) turtles.

On 12 November 1984, 6 seven-week old green turtles were acquired from The House of Refuge at Jensen Beach, on Florida's Atlantic Coast. Their straight carapace lengths (SL) and weights were 7.1–7.4 cm and 54–56 g, respectively. They were raised in captivity until 8 May 1985, when all six were released just south of Wiggins Pass in Collier Co., Florida, USA. The smallest, NNK880, measured 13.2 cm SL, 10.54 cm straight width, and weighed 344.2 g. This animal was recaptured ca. 27 October 1998, ca. 2 km off the Cuban coast and ca. 2 km north of Purta Lucrecia (Fig. 1). The captors considered the animal to be in 'good health' with an estimated weight of 45 kg.

While information on long-distance tag returns is received only sporadically, such data provide insight into the location of areas that may afford suitable foraging habitat for both juvenile (NNK880) and adult turtles. Tag returns from loggerhead turtles captured in Cuba and Mexico suggest that a percentage of the post-nesting females from Florida's southwest coast migrate to these

TABLE 1. Non-nesting loggerhead tag returns from Southwest Florida, USA.

Tag # tagged	Date	Location tagged	Date recaptured	Country
AAV836	26 Jun 87	Keewaydin Is.	1 Nov 88	Cuba
PPS574	29 July 88	Casey Key	9 Jan 91	Mexico
QQE610	24 July 90	Casey Key	15 Mar 96	Cuba
QQP188	8 Jun 93	Manasota Key	14 Sept 93	Cuba

areas after the reproductive season (Table 1). Fig. 1 depicts the approximate locations where these turtles were captured. Unfortunately, the information on the tag return from Mexico indicated only that the animal had been captured off the coast of Yucatan.

The data from these tag returns provide some insight into the migratory movements of post-nesting loggerheads from southwest Florida. In particular, the extent and geographic location of the Cuban coastline suggest that it offers suitable foraging habitat for at least some portion of the loggerhead turtles that nest in southwest Florida. Though limited in number, the tag return data presented here support this suggestion. Undoubtedly, studies utilizing satellite telemetry will more clearly delineate the migratory routes and foraging areas of the loggerhead turtles which nest on Florida's west coast. From another perspective, this information is also valuable in that it clearly demonstrates the need for international cooperation when addressing conservation issues related to sea turtle protection. Without such cooperation, sea turtle populations worldwide are more likely to face an uncertain future.

We thank Jerris Foote (Mote Marine Laboratory) and John McCarthy (Sarasota County Community Services, Parks and Recreation Unit) for allowing us to use their tag return data. We also thank Julio Gomez Gonzalez, Carlos Tamayo Hernandez, and Jose Ottenwalder for their willingness to send the tag data from the recaptured turtles to the National Marine Fisheries Service in Miami. Thanks to the many field technicians and volunteers who, over the years, have tagged many turtles on nesting beaches in southwest Florida. We also appreciate the assistance of Peter Eliazar of the University of Florida's Archie Carr Center for Sea Turtle Research.

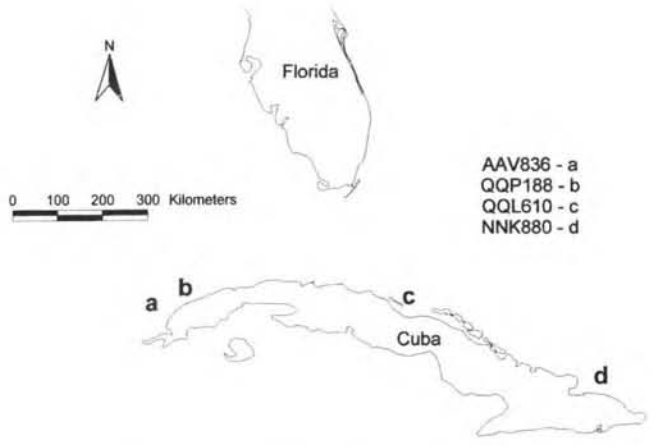

FIG. 1. Map indicating capture locations of tagged sea turtles.

Submitted by **DAVID S. ADDISON**, The Conservancy of Southwest Florida, 1450 Merrihue Drive, Naples, Florida 34102, USA (e-mail: davea@conservancy.org), and **MAURA KRAUS**, Collier County Natural Resources Department, 3301 East Tamiami Trail, Naples, Florida 34112, USA (e-mail: MauraKraus@colliergov.net).

TRIONYX MUTICUS (Smooth Softshell Turtle). **FORAGING.** At 1000 h on 24 June 1998, I observed through binoculars 10 softshell turtles, *Trionyx muticus* and *T. spiniferus*, in the Canadian River at the NM 419 bridge in San Miguel County, New Mexico, USA. I hand captured two of the *T. muticus*, a male 80 mm plastron length and a juvenile female 88 mm plastron length, in a small (~1 x 3 m), shallow sandbar pool separated from the main stream by ca. 10 m. Also in the pool were one partially eaten fresh carcass of a hatchling cliff swallow (*Petrochelidon pyrrhonota*), on which the turtles were observed feeding, and two cliff swallow eggshells. Another freshly killed hatchling cliff swallow was on the sand ca. 30 cm from the pool. *Trionyx* tracks led from the pool to and around the partially eaten carcass. Both the hatchlings and eggshells apparently had fallen from the numerous active cliff swallow mud nests attached to the underside of the bridge directly above.

Although *Terrapene carolina* is known to feed on passerine birds killed at TV towers (Alsop and Wallace 1978. J. Tennessee Acad. Sci. 53:134), the identified prey in most reports of turtles eating birds are young waterfowl (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington D.C. 578 pp.). Smith (1956. Handbook of Amphibians and Reptiles of Kansas, Univ. Kansas Mus. Nat. Hist. Misc. Publ. No. 9) stated that the diet of *Trionyx muticus* included "perhaps young birds." However, Webb (1962. Univ. Kansas Publ. Mus. Nat. Hist. 13:429–611) thought Smith's statement erroneous and in fact likely referred to waterfowl eaten by *T. ferox*, as they are known to do (Webb, *op. cit.*). *Trionyx muticus* is known to feed on a large variety of terrestrial and aquatic invertebrate, vertebrate, and plant prey (Webb, *op. cit.*; Plummer and Farrar 1981. J. Herpetol. 15:175–179). For male *T. muticus* in the Kansas River, >65% of the diet consisted of terrestrial invertebrates that had fallen into the water (Plummer and Farrar, *op. cit.*). Feeding on hatchling terrestrial birds appears to be yet another expression of the highly opportunistic feeding behavior of this primarily carnivorous species.

I thank Charles Painter for comments on the manuscript.

CROCODILIA

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **WINTER MORTALITY.** Restoration of the American alligator within its presumed historical range in Arkansas began following its protection in 1972 and extended through the early 1980s (Arkansas Game and Fish Commission [AGFC], unpublished data). Approximately 2800 alligators were released into 42 Arkansas counties, producing an enhanced species range (see Conant and Collins. 1991. Reptiles and Amphibians of Eastern and Central North

America. Third Edition. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.) that far exceeds the currently-depicted natural distribution in the state (Ross and Ernst 1994. Cat. Amer. Amph. Rept. 600.1–600.14).

On 17 March 2001, at ca. 1630 h, an adult male *A. mississippiensis* measuring 312 cm in length was found dead within the riparian zone of Buffalo Slough, a tributary of the Cache River, 2.4 km SW of Egypt (T14N, R1E, S14), Craighead County, Arkansas, USA. This location lies at the northwestern extreme of the species' range in the United States (Conant and Collins, *op. cit.*). The alligator, discovered by two local youths (Joey Graham and Tim Lamb), was reported to an AGFC wildlife officer (Butch Wilkins) who immediately transported the specimen to Arkansas State University within the same county. The specimen, which had begun necrosis but exhibited no external wounds or signs of decay, was placed in a freezer at the Department of Biological Sciences at 2030 h. AGFC biologist Sam Barkley (who was involved with the alligator restocking program and who examined the specimen), stated that this alligator was not one of the original juvenile specimens released in this part of the state. Presumably, the animal died from exposure during a flooding episode and subsequent cold snap that occurred in the area one week prior to its discovery. This alligator represents the largest specimen ever reported from northeastern Arkansas.

The alligator was deposited into the Arkansas State University Museum of Zoology herpetological collection (ASUMZ 25591). We thank Sam Barkley for allowing us to salvage the alligator and for providing insight into its demise.

PALEOSUCHUS TRIGONATUS (Schneider's Smooth-fronted Caiman) **NESTING.** Natural history and nesting patterns of forest-dwelling caimans is remarkably lacking due to the difficulty of finding and studying these animals in their remote habitats. In this contribution we document the characteristics, development, and hatching of a *Paleosuchus trigonatus* nest found near the Tiputini River in the Ecuadorian Amazon Basin.

The nest was discovered serendipitously on 30 September 1999 while walking in a sector of *terra firme* forest at least 2 km away from the main river and 4.5 m from a shallow stream ca 1 m wide. The nest was at the base of a tree that had a broken branch, producing a gap in the canopy. This resulted in the nest being located under ca. 82% canopy coverage in the area that received the most direct sunlight.

The nest was built with decomposing leaf litter, small branches, and soil. Small roots were found throughout, indicating that it was not recently constructed. The nest was of typical size for caimans, with a diameter of 1.40 m, and a height of 39 cm. The egg chamber was located in the center of the leaf pile and was 18 cm long, 22 cm wide, and 31 cm deep at its deepest point. The nest contained 16 fertile eggs that were on average 68.65 ± 3.3 cm long, 43.61 ± 0.61 cm wide and 73.75 ± 3.11 g in weight; and one infertile egg that was 50.8 cm long, 41.7 cm wide and 47 g. By the time of discovery, no band was evident when examining the eggs against a flashlight, but they were opaque enough to assume that the eggs were developing. The bands probably went all the way to the poles.

Daytime temperature was monitored regularly during the first month showing an average of 27°C on the surface and 30°C at the egg chamber. On 27 November the nest was found to have hatched. All the eggs appeared to have hatched successfully (the infertile egg was removed upon discovery). In the shells there were numerous ants that were eating the remains of blood and yolk attached to the shells, which suggests a very recent hatching (probably the previous day at the earliest). On 19 March 2000 we found five juvenile dwarf caimans within 100 m from the nest (see measurements in Table 1) and no other crocodilian was found in the creek.

The juveniles were found spread out in both directions of the creek, not clumped in a group and when they were caught they were very feisty and not prone to exhibit distress calls, unlike other juvenile caimans. Day and night surveys of the small creek as far as 500 m in both directions failed to reveal the presence of any adult caiman suggesting that the female did not guard the nest or neonates.

It is difficult to speculate about the survival of the clutch as there was a large flood at about the time of hatching (and before we found the hatchlings) that could have moved some of the hatchlings down the river. However, tiger herons (*Tigrisoma lineatum*) do occur in the area and were often seen in this same habitat in hunting position. It is interesting that the placement of the nest was right below a gap in the canopy such that it received direct sun during some hours of the day. Such combination of a gap in the canopy and proximity to a creek might be important cues that the female uses in order to built a successful nest.

Data were collected during the activities, and as a byproduct, of a course in tropical ecology offered by Boston University and Universidad San Francisco de Quito at Tiputini Biodiversity Station. We thank Mayer Rodriguez, Hendry Navaez, Franklin Narvaez, Jaime Guerra, and Bradley Kline for their help in the field, and K. Swing, T. Kunz, and D. Romo for editorial comments on the manuscript.

PALEOSUCHUS TRIGONATUS (Schneider's Smooth-fronted Caiman). **HABITAT**. Current information on the habitat of *Paleosuchus trigonatus* indicates that, in the central Amazonia region of Brazil, this species is restricted to small forest streams. Magnusson (1985. Amazoniana 9:193–204) suggested that individuals of this species are found in large rivers only near the mouths of small forest streams and that such individuals may be transient or might be colonizing habitats from which other species have been extirpated by humans and that most such transients should be juveniles and adult males (Magnusson 1985, *op. cit.*; 1989. *In* Crocodiles: Their Ecology, Management and Conservation, pp. 101–109. Spec. Publ. IUCN/SSC Crocrocodile Specialist Group). Here I report on the presence of several male and female *P. trigonatus* on a medium-sized river (20–40 m wide) in central Amazonia. These observations were made while accompanying the Waimiri Atroari Indians on hunting trips as part of my Ph.D. fieldwork on subsistence hunting and its effects on wildlife populations.

The Alalaú (00°19'072"S, 60°18'359"W) is a navigable river located almost entirely inside the Waimiri Atroari Indigenous Reserve. Several rapids and waterfalls are present along its course and are visible during the low water periods in the region (September to January). The shore consists primarily of "terre firme" (upland) forest. Lakes occur only at the river mouth and there is a portion of flooded forest (Igapó forest) located 20 km downstream from where my observations took place. *Caiman crocodilus crocodilus*, *P. palpebrosus* and *Melanosuchus niger* also occur inside the Reserve area but *M. niger* is not found in the portion of the river where these observations were made. *Caiman c. crocodilus,* and *P. palpebrosus* are known to occur only in the Igapó forest. All caiman species are eaten without preference by the Waimiri Atroari.

On the night of 14 September 1999, four Waimiri Atroari Indians and I canoed a 7 km section of the Alalaú River, located nearly 100 km upstream from the river mouth, in search of caimans. Estimated river width ranged from 20 to 30 m in this portion of the river. Hunting took place from 1935 h to 0100 h. Caimans were sighted with the help of hand lights and killed with harpoons and shotguns (16–20 gauge). Fourteen caimans were spotted and the Indians managed to kill six, all of which were *P. trigonatus*. This sample consisted of four males and two females. The size of the individuals killed indicated the presence of juvenile and adult males and females in the Alalaú River (Males TL [cm]:157, 121, 136, 113; females: 100, 103). Three out of four caimans killed by the Waimiri Atroari in a separate hunting trip in the Igapó forest (20 km downstream) in September 1998 were male *P. trigonatus* (3.5, 7.6 and 9 kg) indicating that this species also occurs here. The fourth individual was *P. palpebrosus.*

These observations agree with some of Magnusson's findings (Magnusson 1985, *op. cit.*) at least regarding the Igapó forest. The frequent occurrence of adult male and female *P. trigonatus* in a large river surrounded by "terra firme" forest, however, indicates that this species may occur in broader habitat types in the central Amazon region than previously thought. In Suriname, adult *P. trigonatus* are known from large rivers (Ouboter 1996. Ecological Studies on Crocodilians in Suriname: Niche Segregation and Competition in Three Predators. SBP Academic Publishing, 147 pp.), much like my observations here.

Caiman crocodilus crocodilus seemed to be much rarer in this part of the river than in portions close to the mouth and in other rivers inside the Reserve where I did some night searches. Data on habitat characteristics of *C. c. crocodilus* for the central Amazon region indicate that this species prefers open, grassy habitats (Ouboter 1996, *op cit.*). These habitats are not present in the upper Alalaú River where *P. trigonatus* were hunted. Although in Suriname *P. trigonatus* and *C. c. crocodilus* are found syntopically in some places, habitat segregation between these species implies competition (Ouboter 1996, *op.cit.*). In the case of the Waimiri Atroari area, the absence of suitable habitat for *C. c. crocodilus* in some portions of the Alalaú River might have favored the occurrence of a population of *P. trigonatus* in a large river.

I thank the Waimiri Atroari people for kindly allowing me to work in their area and participate in their hunting trips, and Bill Magnusson for revising the manuscript. Part of this research was funded by the Brazilian Research National Council (CNPq) and by the World Wildlife Fund-Programa Natureza e Sociedade.

LACERTILIA

ANOLIS LOYSIANUS (NCN). **DIET**. *Anolis loysianus* is endemic to Cuba, found islandwide, but is scarce. Its food habits in nature are unknown (Rodríguez Schettino 1999. *In*: L. Rodríguez Schettino [ed.], The Iguanid Lizards of Cuba, University Press of Florida, Gainesville. 384 pp.). Reviewing the herpetological collection of the Instituto de Ecología y Sistemática, La Habana, Cuba, I found three female *A. loysiana* (CZACC 4.1603–4.1605) which were collected on 20 October 1956, at Soroa, Sierra del Rosario, Pinar del Río province (22°47'N, 83°01'W). Because of the scarcity of information regarding this species, I examined the stomach contents of these three specimens.

The lizards were measured (SVL, head length [HL], and head width [HW]) and dissected to open the stomach. Prey items were identified to the lowest taxon possible. For each food item obtained I measured length using an ocular micrometer.

The lizard measurements (mm) are as follows: specimen 4.1603

TABLE 1. Prey items consumed by three female *Anolis loysiana* from Soroa, Sierra del Rosario, Pinar del Río province, Cuba. Numbers indicate the number of items found in each lizard (length of the items in mm).

Prey Type	Lizard Specimen Number		
	CZACC 4.1603	CZACC 4.1604	CZACC 4.1605
Hymenoptera:			
Formicidae	6 (1.5)		4 (1.5)
Coleoptera:			
Cucujidae	1 (1.5)		
Cantharidae		1 (5.0), 1 (6.0)	
unidentified		3 (2.0)	
Larva	1 (4.0)		
Arachnida:			
Araneae			1 (3.0)
Pseudoscorpionida	1 (3.0)		

(SVL = 37.5, HL = 10.7, HW = 7.3); specimen 4.1604 (SVL = 37.1, HL =11.0; HW = 7.3); specimen 4.1605 (SVL = 40.5, HL = 11.3, HW = 7.7). All of these specimens were considered adults, as the smallest had one egg in its right oviduct (4.4 mm long, 3.0 mm wide).

The dietary data obtained are presented in Table 1. Ants (Hymenoptera, Formicidae) were the most frequently consumed prey (10 items in two lizards), followed by Coleoptera (7 items in two lizards). In this very small sample, the largest female ate the smallest prey, and the smallest lizard, the biggest prey. This is contradictory to the general rule that predator and prey sizes are positively correlated (Schoener 1971. Ann. Rev. Ecol. Syst. 2:369–404), but the small sample size must be taken into account.

I thank Ileana Fernández García for identification of the prey items and Ada Chamizo Lara, Vilma Rivalta González, and Luis de Armas Chaviano for their helpful comments on the manuscript.

Submitted by **LOURDES RODRÍGUEZ SCHETTINO,** Departmento de Vertebrados, Instituto de Ecología y Sistemática, C. de Varona km 3.5, Boyeros, CP 10800, AP 8029, La Habana, Cuba; e-mail: ecologia@unepnet.inf.cu.

ANOLIS MESTREI (NCN). **THERMAL HABITAT.** *Anolis mestrei* is an interesting and beautiful species that lives mainly on rocks in shaded sites of the westernmost region of Cuba. The only previous data concerning temperature preperences of this endemic to Cuba is the mean air temperature of 26°C at Sierra de la Güira in April (Rodríguez Schettino 1999. *In*: L. Rodríguez Schettino [ed.], The Iguanid Lizards of Cuba, University Press of Florida, Gainesville. 384 pp.).

During field work at Soroa, Sierra del Rosario, Pinar del Río Province (22°47'N, 83°01'W) on 15 June 1995, between 1100 h and 1400 h, we captured a small sample of *A. mestrei*. The collecting site is a secondary evergreen forest, very wet and shaded, with limestone cliffs and outcrops running along the Manantiales River.

Lizards were captured and their body temperatures were obtained with a cloacal quick-reading thermometer (0–50°C) at the place of capture. Using the same thermometer, the air temperature was obtained as near as possible to the site that each lizard was first seen. Additionally, the type of substrate and the illumination condition over the site were recorded for each lizard, seen or captured. No running or escaping lizards were considered for the temperature analysis.

Lizards were found on rocks (79%) and on tree trunks adjacent to cliffs (219%). All but two lizards were seen in shaded sites. The two not found in shaded sites were both males found under filtered sun.

There were no statistically significant differences between air and body temperatures for males or females, or between sexes (Table 1). This suggests that *A. mestrei* is a thermopassive lizard that maintains its body temperature passively from its thermal habitat in a place where the cost of thermoregulation should be high due to a scarcity of available sites for basking.

We thank Kevin de Queiroz and Jonathan B. Losos for logistical support of this research and Vilma Rivalta González and Luis F. de Armas for their useful comments on the manuscript.

TABLE 1. Air temperature and body temperature in °C for male and female *Anolis mestrei* from Soroa, Pinar del Río province, Cuba. N = number of lizards; Sx = standard error of the mean; *p* = probability of error (from estimated Student t-test); s = significance; n.s. = no significant difference; numbers between parentheses = range of temperatures.

	Air Temperature			Body Temperature				
Males	N	Mean	Sx	N	Mean	Sx	*p*	s
	7	28.1 (26.2–29.6)	0.39	7	28.2 (26.4–29.4)	0.40	0.18	n.s.
Females	8	28.2 (26.2–28.8)	0.30	8	28.0 (27.4–28.8)	0.15	0.59	n.s.

ANOLIS SAGREI (Brown Anole). **PREDATION.** I witnessed an adult great egret (*Casmerodius albus*) foraging on *Anolis sagrei* lizards in a flower bed between a busy Publix grocery store parking lot and U.S. 441 near the junction of NW 39th Avenue, Gainesville, Florida, USA, on 3 November 2000. My attention was drawn initially to the bird at 0955 h (EST) as it moved through a bed of giant border grass (*Liriope muscari*). I walked within 5 m of the animal, after realizing it was feeding on lizards that it grabbed from the leaves of these 0.8 m tall plants. The egret was deliberate in its movements as it stalked each lizard. It moved between the rows of plants and grabbed and swallowed four, live, medium-sized lizards, either non-territorial males or mature females, within 5 minutes. The bird wandered off at 1000 h, continuing its foraging behavior, along a 1.3 m tall, severely-trimmed hedge row of Indian hawthorn (*Rhaphiolepis* cf. *indica*) immediately adjacent to the parking lot. Neither my presence, nor that of traffic in the parking lot or the busy street, seemed to affect the bird's behavior. The most striking aspect of this observation was that this native wading bird was feeding on an exotic lizard, in exotic vegetation, in a completely exotic terrestrial environment, near an active parking lot and one of the busiest roads in Gainesville, Florida.

I thank Barry Davis, Herbarium, Florida Museum of Natural History, for plant identifications.

CTENOSAURA OEDIRHINA (Roatán Spiny-Tailed Iguana). **BEHAVIOR.** During habitat surveys for reptiles on 4 July 2000 at ca. 1100 h, we searched a portion of the mangrove swamps on the eastern end of Isla Roatán, Islas de la Bahía, Honduras. The particular area where we made our observations is on the island's southern shore near the center of the mangrove expanse (ca. 4 km

x 2 km). According to our boat captain, this is an area rarely, if ever, visited by humans because of the lack of economically attractive features and a high density of biting sand flies. During our foray deeper into the mangrove growth, we encountered a group of ca. six *Ctenosaura oedirhina* of various sizes which were basking on mangrove branches and the sandy substrate. Our arrival was quiet enough to allow us to come within ca. 10 m of one of the larger individuals. When it became aware of the intrusion, it issued a loud squawk from its basking position on the sandy substrate, turned, and fled through a shallow saltwater pool (depth ca. 0.3–0.7 m) into a waterlogged cluster of mangrove roots, where it disappeared from sight. At the issuance of the squawk by the first individual, all other individuals fled, some splashing through the same saltwater pool as the squawker, some along mangrove branches. Based on the sequence of events, we consider the escape of the group to be a direct result of the vocalization, and not of our movement or the movement of the vocalizing individual. The total time elapsed from vocalization to disappearance of the last animal from sight was less than 15 s.

Our observation of a vocalization by a spiny-tailed iguana is unusual for three reasons. Firstly, iguanas in general are not known to issue vocalizations of any kind, even when in distress from predator pressure. If any vocalization such as the one we observed should occur in green iguanas, for example, it should have been noticed by iguana researchers and hunters throughout the neotropics. In work with *Ctenosaura similis*, Paul Gier (pers. comm.) observed only hissing during handling and observed no vocalizations during male combat or reproductive behaviors. Secondly, the use of this vocalization as an apparent warning cry may indicate a greater degree of social involvement by these iguanas than previously assumed. Sudden appearance of a predator in *C. similis* habitat results in the scattering behavior we observed (Paul Gier, pers. comm.), but this response was presumably the result of individual positioning and visual contact with the predator, as observed in *C. pectinata* (Richard Durtsche, pers. comm.), and not caused by a warning call. It is possible that a vocalization is advantageous to *C. oedirhina* for timely escape in a habitat comprising dense mangrove root tangles and foliage that impede the lizards' visual ranges. Lastly, several of the lizards escaped into a saltwater pool whose depth could only be overcome by noisy splashing and floating towards a root tangle on the far side of the pool. Based on the habitat substrate characteristics, it was obvious that the entire mangrove patch was occasionally inundated by salt water, though it was above the regular tide line. A certain degree of tolerance to salt water has been described in iguanian lizards that occasionally foray into salty or brackish areas (e.g., *Uta tumidarostra*; Hazard et al. 1998. Copeia 1988:231–234) and this capacity is highlighted by the behavior and food choices of marine iguanas (Wikelski and Hau 1993. J. Biol. Rhythms 10:345–360). In order to be effective in this type of mangrove habitat, this population of *C. oedirhina* has an obvious advantage if it is better adapted to salty conditions, since much of its food source and much of its activity revolve around salty conditions. Escape into the dark root tangles makes for an effective hiding strategy as the damp hideaway might prevent potential avian or mammalian predators from further pursuit.

We thank Richard Durtsche, Gunther Köhler, and Paul Gier for sharing their experiences with ctenosaurs and for comments on the manuscript. This is Tropical Field Biology Contribution No. 3 from the Department of Biology at La Sierra University.

DRACAENA PARAGUAYENSIS (Paraguayan Caiman Lizard). **REPRODUCTION**. *Dracaena paraguayensis* is one of the largest South American teiids. It is oviparous, with semi-aquatic and semi-arboreal habits. Its diet is very specialized, consisting mainly of large snails (Pough et al. 1998. Herpetology. Prentice Hall, Upper Saddle River, New Jersey. 577 pp.). The genus *Dracaena* contains two species: *D. guianensis* from Amazonian rain forest and *D. paraguayensis*, restricted to parts of the Pantanal subject to flooding by the Alto Paraguai River in the states of Mato Grosso and Mato Grosso do Sul, Brazil and in Paraguay (Vanzolini and Valencia 1966. Arq. Zool. 13:7–35; Strüssmann 1997. Herpetol. Rev. 28:151).

Little is known about the reproductive biology and natural history of these species. The available information concerning *D. guianensis* has been acquired in captivity, including aspects of reproduction (Vanderhaege 1984, Bull. Chicago Herpetol. Soc. 20:56–57), foraging behavior (Vanzolini 1961. Papéis Avulsos Dep. Zool. Sec. Agr. S. Paulo 14[25]:237–242; Vanzolini 1964. Herpetologica 20:207), measurements of eggs (Goeldi 1902, cited in Avila-Pires 1995. Lizards of Brazilian Amazonia. Nationaal Natuurhistorich Museum, Leiden, The Netherlands. 706 pp.). The only report relating to reproduction in *D. paraguayensis* describes courtship behavior (Strüssmann 1997, *op. cit.*).

On 6 February 1999, in the area of Jacadigo Bay, municipal district of Corumbá (19°01'S, 57°38'W), western Pantanal of Mato Grosso do Sul, David de Almeida and Luís Wagner de Almeida collected five *D. paraguayensis* eggs. The eggs were found in the cavity of an inactive termite nest (ca. 40 cm diam) fixed ca. 1.5 m above the soil to a tree regionally called "canjiqueira" (*Byrsonimia*, Malpighiaceae). According to the collectors, the location of the tree is not subject to flooding, but it is close to Jacadigo Bay.

I measured the mass, length, and width of the eggs. The eggs of *D. paraguayensis* appear similar to those reported for *D. guianensis* by Vanderhaege (1984, *op. cit.*) and Goeldi (1902, cited in Avila-Pires, *op.cit.*) (see Table 1).

The eggs were incubated in a lidded, plastic container, semi-buried in moist powdered "xaxin." An external lamp was used as a heat source and the container was regularly monitored to check humidity, temperature and presence of fungi in the substrate. The substrate was replaced twice when a proliferation of small insects was detected. Two eggs, which seemed dehydrated when found, subsequently turned a dark and were attacked by fungi and small insects. These were removed from the container and dissected on 19 April (after ca. 73 days). I verified that they contained no embryos.

The three remaining eggs hatched on 7, 8 and 11 June, at 121, 122 and 125 days after the eggs were collected. It is important to note that since the date of oviposition is not known, we can only

TABLE 1. Measurements of eggs from *Dracaena paraguayensis* (N = 5) and *D. guianensis*. Data are mean (range, standard deviation).

	D. paraguayensis (N = 5)	*D. guianensis* (N = 5)*	(N = 2)**
Length (mm)	71.62 (69.7–73.6, SD = 1.61)	75	74.5
Width (mm)	37.5 (36.27–38.52, SD = 0.92)	32	38.25
Mass (g)	54.71 (53.83–55.48, SD =0.69)	—	—

* Goeldi (1902 cited in Avila-Pirea 1995. Lizards of Brazilian Amazonia. Nationaal Natuurhistorich Museum, Leiden, The Netherlands. 706 pp.).
** Vanderhaege (1984. Bull. Chicago Herpetol. Soc. 20[2]:56–57).

infer that the incubation time of the eggs of *D. paraguayensis* is at least four months. At hatching, the hatchlings were not aggressive and were easily handled. An "egg tooth" remained for nearly seven days. At hatching and after ca. 70 days, the following measurements were taken: head length (from anterior edge to the posterior area of the tympanum), SVL, tail length, TL, and body mass (see Table 2).

The aquatic gastropods *Pomacea caniculata* and *P. scalaris* (Pulmonata) were used as food for the hatchlings. These snails are found in great abundance in the area where the eggs were collected and the probability that they constitute the main dietary resource of *Dracaena* in its natural environment is high. Mollusks offer high protein and caloric content (Bezerra et al. 1997. Rev. Cient. UFMS 4[1]:10–17). All three specimens are being maintained in the zoology laboratory of Centro Universitário de Corumbá (UFMS).

Eggs found inside termite nests were also reported for *D. guianensis* (Goeldi 1902, cited in Avila-Pires, *op. cit.*). Oviposition inside termite nests is common among Neotropical lizards (Fitch 1970, Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52, 247 pp.). Since this is the first report of oviposition of *Dracaena* in a natural environment, it is important that further studies be made before assuming that this is a pattern for the genus.

Two eggs of *D. guianensis* laid in captivity hatched with incubation times of 179 and 192 days (mean of 185 days or about six months), with hatchlings measuring 260 and 270 mm TL and each weighing 28 g (Vanderhaege 1984, *op. cit.*). These hatchlings were smaller than the *D. paraguayensis* reported here (compare with Table 2).

TABLE 2. Measurements of hatchlings from *Dracaena paraguayensis* (N = 3). Data are mean (range, standard desviation). All length measurements in mm.

	First day	After 70 days
Body mass (g)	53.7 (52.3–54.5, SD = 1.26)	66.7 (57.1–72.5, SD = 8.42)
Head length	35.5 (35–36, SD = 0.71)	38.37 (36.99–39.54, SD = 1.29)
Snout–vent length	109 (105–115, SD = 5.13)	128 (120–135, SD = 7.64)
Tail length	177.7 (176–179, SD = 1.53)	202.67 (188–210, SD = 12.7)
Total length	287 (281–293, SD= 6)	331 (308–345, SD= 20.1)

The reproductive activity and cycle of *D. paraguayensis* are unknown. Courtship behavior was observed in January (Strüssmann 1997, *op. cit.*). No information regarding development period before oviposition, number of eggs, or number of clutches per reproductive season is known. Considering Strüssmann's observation, we can infer that oviposition would occur in the middle of the year and that a second reproductive attempt is possible. In the Pantanal, the climate is typically tropical with winter being dry and warm. Even though there is little rainfall in the winter, there is still a period of flooding, which could induce a second reproductive attempt. Cases of more than one annual reproductive investment are expected in the tropics (Fitch 1970, *op. cit.* and Pough et al. 1998, *op. cit.*) but further studies on the biology of the species should be carried out to determine if this is true for *Dracaena*.

I thank David de Almeida and Luís Wagner de Almeida for collection of eggs; Christine Strüssmann for incentive and providing important literature; José Ragusa Netto for giving suggestions and looking after the hatchlings; Janaína O. Arruda and Simone Y. Benites Silva for laboratory assistence; Maria Angélica O. Bezerra and Iria H. Ishii for loan of equipment.

Submitted by **VANDA LÚCIA FERREIRA**, Depto. de Ciências do Ambiente, Centro Universitário de Corumbá, Universidade Federal de Mato Grosso do Sul, Caixa Postal 252, 79301-970 Corumbá, Mato Grosso do Sul, Brazil; e-mail: vanda@pantanalnet.com.br.

HELODERMA HORRIDUM (Beaded Lizard). **REPRODUCTION.** The purpose of this note is to report on a histological examination of testes from four *Heloderma horridum* and to comment on the reproductive cycle of this species. The beaded lizard is known from the Mexican states of Sonora, Sinaloa, Nayarit, Jalisco, México, Michoacán, Colima, Morelos, Guerrero, Oaxaca, and Chiapas (Flores Villela and Gerez. 1994. Biodiversidad y Conservación en México: Vertebrados, Vegetación y Uso del Suelo, Comision Nacional para el Conocimiento y uso de la Biodiversidad y Universidad Nacional Autónoma de México, 439 pp.). There are reports of mating occurring in the fall (Alvarez del Toro. 1982. Los Reptiles de Chiapas. Tercera Edición, Colección Libros de Chiapas, Serie Especial, Publicacion del Instituto de Historia Natural, Tuxtla Gutiérrez, Chiapas, México, 248 pp.; Ramírez Velázquez and Guichard Romero. 1989. El Escorpión Negro: Combates Ritualizados. Instituto de Historia Natural, Tuxtla Gutiérrez, Chiapas, México, 20 pp.) and male combat in the fall (Beck and Ramírez-Bautista. 1991. J. Herpetol. 25:481–484; Alvarez del Toro, *op. cit;* Ramírez Velázquez and Guichard Romero, *op. cit*). However there is, to our knowledge, no histological information on the time of sperm formation (spermiogenesis).

Testes were formalin fixed and preserved in alcohol. They were dehydrated in ethanol, cleared in xylene and embedded in paraffin. Histological sections were cut at 5 µm and stained with hema-

toxylin followed by eosin counterstain. Two *H. horridum* were from the herpetology collection of the University of Arizona, Tucson, (UAZ). One, UAZ 35420 measured 343 mm, snout-vent length, SVL and was a road-kill collected 4 September 1956, 18 km (by rd) SE Elota, Sinaloa. This testis was undergoing spermiogenesis and the tubules of the epididymis were enlarged and contained sperm. The second, UAZ 37847 measured 320 mm SVL and was collected 3 August 1973, ca. 32 km N Manzanillo, Colima. This testis was in early recrudescence (proliferation of cells for the upcoming spermiogenesis) and contained mainly primary spermatocytes. Testes from two additional *H. horridum* road-kills collected by the junior author were also examined. One, from Alamos, Sonora collected 6 August 1989, measured 355 mm SVL and contained regressed testes with spermatogonia the predominant cells. Some primary spermatocytes were present suggesting the next spermatogenic cycle was starting, but not yet fully underway. Tubules of the epididymis were small and did not contain sperm. The second, from Chamela, Jalisco, measured 444 mm SVL and was collected 1 October 1987. This testis had undergone autolysis making it impossible to interpret cellular composition. However, the large sizes of the seminiferous tubules and great numbers of intratubular cells suggested spermiogenesis was in progress. The vas deferens was packed with sperm.

The finding of one road-kill spermiogenic male from September, along with observations of autumn mating (Alvarez del Toro, *op. cit.,* Ramírez Velázquez and Guichard Romero, *op. cit.*) and male combat (Beck and Ramírez Bautista, *op cit.* Alvarez del Toro, *op. cit;* Ramírez Velázquez and Guichard Romero, *op. cit.)* indicate that *H. horridum* indeed breeds during autumn. This is in marked contrast to the reproductive cycle of the Gila monster, *H. suspectum* in which sperm formation occurs in May and June (Goldberg and Lowe. 1997. J. Herpetol. 31:161–166) and mating occurs in the spring (Lowe et al. 1986. The Venomous Reptiles of Arizona. Arizona Game and Fish Department, Phoenix, 115 pp; Beck. 1990. J. Herpetol. 24:54–68).

We thank Charles H. Lowe (University of Arizona) for permission to examine *H. horridum.*

MABUYA MACRORHYNCHA (NCN) **ENDOPARASITES**. Reports of helminths infecting the Brazilian skink *Mabuya macrorhyncha* are presently restricted to nematodes (Ribas et al. 1998. An. Sem. Reg. Ecol. VIII, São Carlos - vol. II: 883–894; Vrcibradic et al. 2000. Amphibia-Reptilia 21:307–316). Here we present data on helminths associated with *M. macrorhyncha* from a locality where this species has not yet been studied.

During a study of the herpetofauna of a "restinga" (coastal sandy habitat) area in Trancoso (16°39'S, 39°06'W), Bahia, Brazil, carried out in November 1999, we collected eight adult *M. macrorhyncha* (three males and five females; SVL range 66–77 mm). Seven of them (87.5%) were infected by helminths. The number of helminth species per individual host varied from one to five (most frequently three) and was not related to lizard SVL ($r = 0.18$; $p = 0.7$). Seven helminth species were recovered from the lizards: one acanthocephalan (unidentified Echinorhynchidae; found only as cystacanths), one pentastomid (*Railietiella* sp; found in larval stage), one trematode (*Paradistomum parvissimum*, Dicrocoellidae), one cestode (*Oochoristica ameivae*, Linstowiidae), and three nematodes (*Parapharyngodon sceleratus*, Pharyngodonidae; *Physalopteroides venancioi*, Physalopteridae; and *Hexametra boddaertii*, Ascarididae; the latter found only as larvae). Voucher specimens of helminths were deposited at the U.S. National Parasite Collection (USNPC 90522–5) and at the Coleção Helmintológica do Instituto Oswaldo Cruz (CHIOC 34421–3). Data on prevalences and infection intensities (*sensu* Bush et al. 1997. J. Parasitol. 83: 575–583) for each helminth species and their respective sites of infection are given in Table 1. *Mabuya macrorhyncha* represents a new host record for *P. parvissimum*, *O. ameivae*, the genus *Raillietiella* and the family Echinorhynchidae.

In spite of the small sample size, our data suggest that the population of *M. macrorhyncha* studied here has a relatively high frequency of helminth infection, with the nematode *P. sceleratus* and the cestode *O. ameivae* being the most prevalent among them.

We thank the Conselho Nacional do Desenvolvimento Cientifico e Tecnológico - CNPQ for grants to DV, CFDR and MVL. DV and CFDR also received financial support from the Fundação do Amparo à Pesquisa do Estado do Rio de Janeiro - FAPERJ (Process E-26/170.385/97).

TABLE 1. Prevalence (in percentage and absolute values) and intensity of infection (mean ± standard deviation, with range in parentheses) of helminths found in *Mabuya macrorhyncha* (N = 8). Species marked with an asterisk were represented only by immature stages.

Helminth	Prevalence (N)	Mean intensity (range)	Site of infection
Acanthocephala			
Echinorhynchidae*	50.0% (4)	3.0 ± 3.4 (1–8)	Stomach wall
Pentastomida			
Raillietiella sp.*	12.5% (1)	1.0 (0–1)	Encysted near lung
Trematoda			
Paradistomum parvissimum	37.5% (3)	8.7 ± 6.7 (1–13)	Gall bladder
Cestoda			
Oochoristica ameivae	62.5% (5)	9.8 ± 3.9 (6–14)	Small intestine
Nematoda			
*Hexametra boddaertii**	12.5% (1)	8.0 (0–1)	Body cavity
Parapharyngodon sceleratus	75.0% (6)	1.8 ± 1.3 (1–4)	Intestines
Physalopteroides venancioi	12.5% (1)	4.0 (0–1)	Stomach

PHRYNOSOMA CORONATUM (Coast Horned Lizard). **PREDATION and TELEMETRY.** As part of a four-year study on the ecology of *Phrynosoma coronatum* on the SW Riverside County Multi-Species Reserve, California, USA, 45 horned lizards were tracked by radio telemetry (PD-2, Holohil Systems, Ltd.). The radios were attached to the lizards using a modified backpack design (Fisher and Muth 1995. Herpetol. Rev. 26:139–140). Rather than gluing the radio to bicycle inner tubing (Richmond 1998. Herpetol. Rev. 29:220–221), the radios were sewn (using Spectrafiber, Izorline Intl.) via suture tubes embedded in the radio to a piece of ripstop nylon, cut slightly larger than the radio (25 x 25 mm). Two 6 mm-wide elastic straps were placed over the shoulders, crossed over the ventrum, wrapped under the opposite leg, and sewn in place to the top of the nylon, adjusting to fit the size of the lizard. The straps were also sewn to each other at the crossover point to prevent the animal's escape.

During the study, several individuals were lost to predation, to both verified and unknown causes. For one lizard, a definitive snake predation was observed. On 3 July 1997, while tracking an adult male (47 g, 80.5 SVL) fitted with our backpack and transmitter, we flushed a large (> 1 m) coachwhip (*Masticophis flagellum)* from under a yellow bush penstemon (*Keckiella antirrhinoides*). The radio signal moved with the snake, for a distance of 6 m, at which point the snake retreated into a wood rat (*Neotoma* sp.) nest and evaded capture. During the next seven days, we located the snake twice in a system of impenetrable rodent holes 59 m from the wood rat nest. On 14 July, the radio backpack unit, apparently defecated, was recovered on the surface within 5 m of this site. No other fecal material was found nearby. The radio and backpack were still connected, although the materials appeared fused in a streamlined, longitudinally elongated shape. Lizard scales and toenails were also found adhered to the backpack (Fig. 1).

On two additional occasions (4 June 1996, female, 54 g, 87.2 mm SVL and 20 August 1997, male, 42 g, 87.2 mm SVL), radio assemblies were recovered from the field with identical characteristics to those seen on 14 July 1997. Although the predators were not observed, we believe these lizards also were eaten by snakes, based on their striking similarity to the verified occurrence. Observed predations of horned lizards by birds leave the radio assembly unmolested and, in some cases, the disemboweled lizard has been found still wearing the backpack.

FIG. 1. Remains of *Phrynosoma coronatum blainvillei*, radio, and backpack defecated by *Masticophis flagellum*.

In contrast to LaBonte (this issue), at least three snakes were able to successfully pass the radio and backpack materials. In light of our observations, radio telemetry studies of small lizards should consider the size and texture of the attachment materials relative to their impact on potential predators.

Submitted by **TANDORA D. GRANT** and **ALLISON C. ALBERTS**, Center for Reproduction of Endangered Species, Zoological Society of San Diego, San Diego, California, 92112, USA; e-mail (TDG): tandora@sandiegozoo.org; (ACA): aalberts@sandiegozoo.org.

PHRYNOSOMA CORONATUM (Coast Horned Lizard). **PREDATION AND TELEMETRY.** During a long-term radio-tracking study of *Phrynosoma coronatum*, a clear case of predation by *Masticophis flagellum* was observed. On 8 July 1998, at the University of California Elliot Chaparral Reserve, adjacent to USMCAS Miramar, San Diego County, California USA, an adult horned lizard (male, 22.5 gm, 78.0 mm SVL), fitted with a backpack (Richmond 1998. Herpetol. Rev. 29:220–221) and radio transmitter (PD-2, Holohil Systems, Ltd.), was located on bare ground in the shade of a chamise bush (*Adenostoma fasciculatum*). On 11 July the lizard's signal was tracked to a rodent hole 187 m from the lizard's previous location. We carefully dug into the rodent hole to ca. 50 cm below the surface and found a large *M. flagellum*. The snake evaded capture by entering a system of rodent holes beneath nearby asphalt. On 13 July the signal was tracked to another rodent hole 173 m from its previous location. We carefully excavated to ca. 25 cm and successfully captured the snake (female, 550 gm, 147 cm SVL). In order to retrieve the transmitter, the snake was retained in captivity. On 15 July the snake was x-rayed to determine the location of the transmitter and backpack in the snake's digestive tract. The x-ray showed the transmitter in the area of the snake's stomach with no discernable evidence of the *P. coronatum*. The snake shed and produced a scat on 22 July. Examination of feces revealed undigested leaf litter and digested animal matter but no signs of the transmitter or backpack. The transmitter could be felt in the snake in the same location as on 15 July. On 10 August the transmitter had not passed and was surgically removed from the snake's stomach. The transmitter and backpack were still attached to each other and, therefore, had caused the whole assembly to become lodged. The snake was allowed to recover in captivity and released at the point of capture in good health on 15 September. On 26 May 1999, it was sighted, identified by the surgical scar, basking on an asphalt road 20 m from its point of capture. The snake appeared to be in good health.

It is apparent from this observation that even a large snake may have difficulty passing a transmitter attached to a backpack. In order to minimize this risk, future designs may attempt to reduce the size of the backpack component when attaching transmitters to lizards.

I thank Ted Case and Andrew Suarez for permitting me to report this observation. Jeff Tracey performed the surgical removal of the transmitter from the snake. Jon Richmond and Sam Sweet provided helpful comments and suggestions.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **MOVEMENT**. There have been only two studies that utilized radio-telemetry to track the movements of the Texas horned lizard. Fair and Henke (1999. J. Herpetol. 33:517) tracked 7 lizards for less than 50 days, 3 lizards for 116 days, and 1 lizard for 139 days and Munger (1984a. Oecologia. 62:351–360) tracked 47 horned lizards for up to 72 days. Therefore, although other aspects of this lizard have been widely studied (for review, see Sherbrooke 1981. Horned Lizards: Unique Reptiles of Western North America. Southwest Parks and Monument Assoc., Globe, Arizona. 48 pp.), little information is available on movements of this lizard, particularly in the northern part of its range.

Two lizards (one male, one female) from Two Buttes State Wildlife Area, Prowers County, Colorado, USA, were radio-tracked during the summer of 1997. Holohil BD-2GI (Holohil Systems Ltd., Carp, Ontario, Canada) radios were attached externally on the dorsal surface of the lizards using silicone sealer, similar to Munger (*op. cit.*), but with the antenna extending posteriorly. The silicone method was employed instead of the backpack method (Fisher and Muth 1995. Herpetol. Rev. 26:139–140) to prevent lizards from becoming entangled in vegetation. Although neither of our lizards was lost to predation, this method of radio attachment may also have the advantage of being passable by snake predators (see Fisher and Muth, *op. cit.*; Labonte, this issue). The obvious disadvantage of this method is that the radio is shed with the skin during ecdysis. Lizards were tracked daily or every other day using a Custom Electronics CE12 148MHz to 149.2 MHz radio receiver (Custom Electronics, Urbana, Illinois).

The female lizard was tracked from 24 June 1997 to 6 November 1997. We tracked this lizard at least every third day until she appeared dormant (was buried relatively deep underground) late in the season, when we located her less frequently until the end of telemetry. This lizard (B97-230) was an adult measuring 79.8 mm SVL and 30.4 mm tail length. She moved a minimum straight-line distance of 744.2 m in 105 days. She moved within a relatively small area, often returning to the same location until 26 July 1997 when she started her longest movement in any given interval (343.1 m in two days). Her longest movement took her away from the immediate area of the roadside ditches she was occupying to an area dominated by sandsage and yucca, where she eventually hibernated. The female lizard was ca. 5 cm underground when tracked on 7 October 1997; however, when tracked on 6 November 1997 she had moved to a new location, ca. 25 cm away, where she had buried ca. 8 cm underground and appeared to be dormant.

The male lizard was tracked from 24 July 1997 to 17 September 1997 when the radio failed. This lizard (B97-374) was an adult measuring 68.6 mm SVL and 33.3 mm tail length. He moved a minimum straight-line distance of 48.3 m in 56 days. This lizard never left the immediate area of the roadside ditches during the telemetry period. The longest movement in any given interval was 15.4 m in two days.

Large movements from foraging grounds to hibernation areas seem likely considering that the primary food source of these lizards are harvester ants (*Pogonomyrmex* sp.) that invade disturbed areas with little vegetation (Tabers 1998. The World of Harvester Ants. W. L. Moody , Jr., Nat. Hist. Ser., No. 23, Texas A&M Univ. Press. 213 pp.) like roadside ditches. Moving to areas with higher vegetation density and a greater amount of ground litter would provide better insulation for buried lizards during hibernation. However, this large movement was not seen in the male radioed lizard.

These lizards may be utilizing optimal foraging, as described by Munger (1984. Amer. Nat. 123:654–680) by moving between different foraging sites within an area in order to increase efficiency of foraging. Optimal foraging was suspected in the radioed lizards as they would often return to previous foraging sites after spending days away from them. Although these lizards did not move great distances (usually less than 5 m) away from an area, they would often return to the exact location.

PSEUDOCORDYLUS MELANOTUS MELANOTUS (Drakensberg Crag Lizard). **COPULATION and AGGRESSION.** Although the reproductive cycles of both male and female *Pseudocordylus melanotus melanotus* have been reported by Flemming (1993, J. Herpetol. 27:103–107; 1993, J. Herpetol. 27:473–478), there have been no observations of mating behavior reported in the literature. At 1320 h on 26 April 2000, I observed a copulation in Suikerbosrand Nature Reserve (between 26°27' and 26°34'S, 28°09' and 28°21'E), ca. 40 km SE Johannesburg, South Africa. The male approached the female who turned away from him. The male then seized the female's right hind leg and shifted his grip to her neck. Copulation was observed for ca. two minutes during which time the female showed no sign of resistance.

Male-male aggression, usually associated with mate guarding and territoriality, is also evident in this population. I observed two males fighting on 2 June 2000 at ca. 1500 h. They were biting each other in the head and neck region, to the extent that one individual was bleeding freely from wounds on his head.

Pseudocordylus melanotus exhibits an asynchronous reproductive cycle; males store sperm in the epididymi until late winter/spring, when the females ovulate (Flemming, *op.cit.*). Mouton and van Wyk (1993. Can. J. Zool. 71:1715–1723) note the existence of unpublished data of mating occurring in fall only (suggesting sperm storage), but also cite Mackay (1993) who found no evidence of sperm storage in females of this species. They also indicate, however, that the population used in their study could be assigned to the subspecies *P. m. subviridis*.

My observation suggests one of two possibilities that need not be mutually exclusive. Either female *P. m. melanotus* in this population ovulate in autumn/winter (coinciding with copulations); and/or they are storing sperm until ovulation occurs in the spring. The intense male-male combat I witnessed further suggests that males are competing for mates in autumn/early winter.

Thanks to Martin Whiting and Hannes van Wyk for valuable input on this note.

TARENTOLA ANNULARIS (White-spotted Gecko). **DIET.** On 29 April 2000 a case of cannibalism was observed for *Tarentola annularis* at Ismailia, Suez Canal University (Old campus: 30°36'41"N, 32°16'37"E), Ismailia Province, Egypt. At 1955 h, an adult (ca. 110 mm SVL) *T. annularis* was observed on the wall of a building ca. 7 m above the ground. The adult lizard was holding a conspecific juvenile (ca. 40 mm SVL) in its jaws. The anterior portion of the body of the juvenile was engulfed, while the posterior half of the body, oriented ventral side up, was suspended from the mouth. A drop of blood was visible on the side of the upper jaw of the adult. The adult made no attempt to hide while under observation, but moved about 10 cm down the wall from where it was first observed. It remained in this position for about 15 minutes, still holding the prey. When the observer moved back some distance and watched the lizard with binoculars, it resumed swallowing its prey. It was recommended by Flower (1933. Proc. Zool. Soc. London 1:735-851) not to house this gecko with other lizards because of its possible cannibalistic tendencies. This is the first record of diet for this species in Egypt (see Saber et al. 1995. J. Egyptian Soc. Parasit:395–406).

THECADACTYLUS RAPICAUDA (Turnip-Tail Gecko). **BEHAVIOR**. The turnip-tail gecko is commonly seen in forested habitats, on tree trunks, and inhabiting abandoned human habitations in the Caribbean (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. 720 pp.), although it lives associated with inhabited human-made structures in the western Amazon (Vitt and Zani 1997. Herpetologica 53:165–179). At Simla, the research station maintained by the Asa Wright Nature Center in Trinidad, two male *Thecadactylus rapicauda* live in a habitat unusual for this species the Caribbean, the eaves of the main residence. There, they share space near a valuable resource: a powerful mercury lamp is mounted above the entrance to the house and operates nightly to attract insects for collection. Beebe (1944. Zoologica, N.Y. 29:145–160) reported that *T. rapicauda* were attracted by light fixtures, but did not consider them residents near them. The lamp at Simla is suspended from the eaves via a broad attachment that divides the eaves into two sections to either side of the fixture. The two male *T. rapicauda* have established territories in these sections on either side of the light from which they forage along the wall of the house for the attracted insects. The geckos have been reliably found in their territories night after night over a period of several years, and we have observed several instances of feeding on insects attracted by the mercury lamp.

On 7 September 2000 at 2230 h, both males were observed in the territory to the left of the lamp, about two body lengths apart. The resident male began an agonistic encounter within seconds of the arrival of the intruder by issuing a sharp, loud hiss that occurred almost simultaneously with a sudden, jerky forward movement in the intruder's direction. A physical encounter that clearly involved head-butting and biting by both males followed the initial threat display. The intruder retreated to the right side of the lamp ca. 60 s after the encounter began.

Our observations support the notion of Vitt and Zani (*op. cit.*) that fighting occurs with some frequency in *T. rapicauda* and may result in injury or tail autotomy. However, no vocalization during agonistic encounters was reported by these authors. Underwood (1962. Carib. Affairs, N.S. 1:1–192) described the call of *Thecadactylus rapicauda* as "a diminishing series of chirps," Turvey and Cooper (1999. Bull. Brit. Herpetol. Soc. 69:20–30) called it a "harsh barking call," and Beebe (*op. cit.*) referred to it as "chock-chick-chick." Johnson (1946. Copeia 1946:108) noted that these geckos emit a "bat-like squeak" when captured. Clearly, none of these reports refers to the hiss we observed. In general, hissing among gekkonine geckos is a response only elicited by a threat (A. M. Bauer, pers. comm.). We submit that this type of vocalization is commonly used by these geckos in agonistic encounters but has not been reported because of the relative scarcity of individuals establishing territories in inhabited buildings.

We thank Ronnie Hernandez for confirming the species identification, and Laurie Vitt and Aaron Bauer for providing input on the manuscript. Funding was provided by the University Research Council of La Sierra University.

Submitted by **HINRICH KAISER** (e-mail: hkaiser@lasierra.edu) and **RAUL E. DIAZ** (e-mail: frog_diaz@hotmail.com), Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

TRIBOLONOTUS GRACILIS (Crocodile Skink). **MATERNAL CARE**. Parental care of ova and neonates has been reported in a variety of scincids. For example, North American skinks of the genus *Eumeces* are known to stay with their eggs throughout the incubation and even defend them against predation by small rodents (Porter 1972. Herpetology. W. B. Saunders Co., Philadelphia, Pennsylvania. 534 pp.). Evans (1959. Copeia 1959:103–110) reported egg brooding, and grooming of neonates by female *E. obsoletus*. Herein, we report the protective maternal care of ova and neonates by three female *T. gracilis* in captivity at the Dallas Zoo.

Little information has been published concerning the behavior of *T. gracilis*, and parental care has never been reported for this species or genus. *Tribolonotus gracilis* is a small black scincid (184 mm mean total length) endemic to New Guinea. This spe-

cies, as well as several other members of the genus, have only one functional ovary and typically invest all their reproductive energy into the production of a relatively large, elongated (21 mm average length) single egg.

On three separate occasions, between 12 October 1999 and 24 February 2000, eggs (usually removed for artificial incubation) were intentionally left in three enclosures, each housing a pair of *T. gracilis*, thus enabling observers to watch for evidence of parental care. Each female deposited one egg under a four-inch piece of cork bark and buried it with sphagnum moss. The cork bark was lifted once a day to check for positioning of the females and their ova for the duration of incubation (ca. 60 days). In all cases the females were found curled around the eggs. In addition to checking female and egg positions, observers touched the eggs to elicit a protective response. In every trial the females responded by lunging and attempting to bite the offending finger. In approximately half of the trials the females vocalized during the attacks. This defensive behavior lasted the duration of the incubation. On 12 different occasions the eggs were left unburied after the trials, but by the next day's observation the eggs had been reburied. After hatching, two neonates were allowed to stay with their parents. The females attempted to protect their offspring using the same behavior as for the eggs. For two weeks the neonates stayed within one centimeter of the females, and on several occasions the neonates were observed resting on the dorsum of the females.

The males remained in the enclosures with the females and their ova, and later the neonates. No male was ever observed guarding an egg or a neonate, and we observed no evidence of aggression by a male directed toward a neonate.

Special thanks to Ardell Mitchell and the staff of the Dallas Zoo Department of Herpetology for their helpful comments on this manuscript.

TROPIDURUS PLICA (Spiny Tree Lizard). **BEHAVIOR.** At Simla, the research station maintained by the Asa Wright Nature Center in Trinidad, there is a 5 m drop from the kitchen window to the rainforest below. The window opening is used to dispose of organic refuse, which serves as a food source for the local fauna and disappears quite rapidly. The partially overgrown vertical wall beneath the window is an attractive territory for *Tropidurus plica* during the day and for *Hemidactylus mabouia* at night. We frequently observed individuals of *T. plica* active on the kitchen wall, which provided excellent cover as well as a resource worthy of defense.

On 8 September 2000 at 0945 h, we observed two adult male *T. plica* in an agonistic encounter. This encounter took place in a small tree near the kitchen wall described above, along a branch used by a resident male. The intruder approached the resident's branch from along the trunk. The resident began the characteristic iguanian aggressive display involving lateral compression and a display of its black dewlap (Debusk and Glidewell 1972. J. Herpetol. 6:139–141) while turning to face the intruder. It then descended two body lengths down the branch for the encounter. The intruder paused in its advance while the resident raised its body and began to head-bob. After only a few head-bobs, the intruder suddenly attacked the resident and delivered a firm bite to the left thigh. The resident bit back with similar intensity at the same spot on his opponent and a tangle ensued. During the tangle, the males clawed at each other with their front limbs while still biting the opponent's thigh. As a consequence of the intense struggle, neither individual was able to maintain a firm foothold and they fell from the branch. They tumbled a distance of 1.5 m, still connected by their bites, but released the hold on each other upon hitting the ground and disappeared into the vegetation. Throughout this encounter, no vocalization was heard.

This report is the first for agonisitic behavior of *T. plica* in the wild, and it confirms some of the findings of Debusk and Glidewell (*op. cit.*). In their laboratory study, Debusk and Glidewell noted similar displays with slight nuances in sequence, but no biting was recorded. We submit that the intensity of the struggle we observed might be connected to the unique food resource below the Simla kitchen window.

We thank Ronnie Hernandez for confirming the species identification and Laurie Vitt and Aaron Bauer for providing input on the manuscript. Funding was provided by the University Research Council of La Sierra University.

Submitted by **HINRICH KAISER** (e-mail: hkaiser@lasierra.edu) and **RAUL E. DIAZ** (e-mail: frog_diaz@hotmail.com), Department of Biology, La Sierra University, Riverside, California 92515-8247, USA.

TUPINAMBIS MERIANAE (Tegu Lizard). **LONGEVITY.** Report of maximum age in reptiles is largely based on specimens kept in captivity and, for lizards, considerable variation in longevity is reported among species (Porter 1972. Herpetology. W. B. Saunders Co. 524 pp.). For *Tupinambis merianae*, the maximum age reported is 13 years (Goin et al. 1978. Introduction to Herpetology. W. H. Freeman, San Francisco, California. 378 pp.). In January 1982, one of us (ASA) received an adult male *T. merianae*, captured at nearby Campinas, São Paulo state, southeastearn Brazil. This animal was an adult male, ca. 330 mm SVL. Based on size and observed growth rate of captive tegus (pers. obs.), this animal was at least three years old. During most of its life this lizard was kept in an outdoor pen (160 m^2), fed twice a week (chicken, rats, beef, fruit), and had free access to water. Over the years, the lizard was kept in a breeding group and grew slowly. In 1992 the lizard was unable to engage in reproductive activity and was separated from the females. A year later, this lizard started progressively to lose muscle mass and its movements became slower and less coordinated. In 1996, its eyes became cloudy and we determined that the lizard would be unable to survive in nature. In captivity, however, he was able to survive until April 1999 (SVL 452 mm; mass 3345 g). Therefore, this specimen lived for a minimum of 17 years, possibly as much as 20 years. In either case, this represents the maximum age reported for the species. The animal was deposited in the collection of the Zoology Department, Universidade Estadual Paulista, Rio Claro, SP, Brazil (DZRC-976).

We thank José Perez Pombal Jr. for the donation of the Tegu specimen.

Submitted by **SIMONE P. BRITO, AUGUSTO S. ABE**, and **DENIS V. ANDRADE**, Departamento de Zoologia, Universidade Estadual Paulista, UNESP, Av. 24-A, 1515, Caixa Postal 199, CEP 13506-900, Rio Claro, São Paulo, Brazil; e-mail (SPB): spbrito@rc.unesp.br.

VARANUS GRISEUS (Desert Monitor). **TOXICITY**. Bites received from many varanid lizards during prey acquisition or in defense may result in significant wounds and secondary bacteremia, producing illness in 1 to 3 days. Except for *Heloderma*, reports on salivary toxins capable of producing immediate systemic effects are generally lacking in Lacertilia. In a case report (Sopiev et al. 1987. Turkmenistan Acad. Sci. 598:615, in Russian) on the toxic effects of a bite from a male *Varanus griseus* (mass = 900 g, SVL = 400 mm, TL = 550 mm), a male keeper was bitten on the right middle finger. The lizard secured its bite for 60 s with a chewing motion. Within 30 minutes the victim reported symptoms including muscular weakness, dizziness, lack of appetite, pain in the eyes, aches and pains in all muscles especially the bottom of the mouth cavity, and pain when swallowing. Difficulty in breathing through the mouth was also noted although no edema was present in the soft palate. One hour post-bite additional symptoms included lymph node pain at the right elbow and arm pit and an increased pulse rate. Here we report two new cases of bites by *V. griseus* with similar physiological effects.

A female keeper at Central Florida Zoological Park was bitten by a *V. griseus* (176 g, 220 mm SVL, 530 total length) as it was being removed from an enclosure after sustaining injuries from a conspecific cage mate. The keeper was bitten on the right hand between the thumb and index finger. Attempts to disengage the bite resulted in a tighter, chewing reflex. The lizard released after ca. 75 s. The wound was immediately cleansed and disinfected with betadine. Within 20 minutes the victim experienced dysphagia, tightness of the chest muscles, and dyspnea. Muscle soreness became generalized during the next hour, progressing downward into the lower extremities. By 1 hour 20 minutes post-bite the facial bones, particularly the frontal, zygomatic, maxilla and mandibular bones became very painful when the skin over them was touched. Within 1 hour 35 minutes post-bite symptoms included dizziness, difficulty in walking due to muscle soreness, and an increase in respiration. The dysphagia and chest tightness increased steadily. By 5 hours 20 minutes post-bite the symptoms began to stabilize. At 16 hours all symptoms had dissipated except muscle soreness in the hands and arms, and a feeling of euphoria was experienced for an additional 4 hours. The bite site remained unremarkable with no swelling, discoloration, or bacterial infection.

A second incident occurred (D. Blanchard, pers.comm.) at Detroit Zoological Park when a male keeper was bitten on the left forearm by a *V. griseus* (ca. 530 mm total length). The duration of the bite was ca. 15 s. Moderate bleeding was noted at the bite site. Within 20 minutes the victim experienced dysphagia and "could hardly swallow." The victim sought clinical treatment one hour post-bite and received epinephrine which relieved the symptoms. The bite wound healed uneventfully.

Auffenberg (1994. The Bengal Monitor. Univ. Press of Florida, Gainesville, 561 pp.) reviewed the mandibular gland as a source of salivary toxins in anguinomorphs and indicated that venom production is suspected in at least some individuals of *V. g. caspius*. Gorelov (1971. Izv. Akad. Nauk. Turkman, SSR, 1:75–76, in Russian) experimentally induced an "intoxificated state" in sparrows and rats following the injection of *V. griseus* saliva (Auffenberg, *op cit.*). In the two new cases reported here, both victims were experienced herpetologists who had received previous bites from other varanid species with no resulting systemic effects. Neither were aware that toxic effects have been suspected in bites from *V. griseus*. We believe that this decreases the likelihood that the symptoms were psychogenic. As salivary peptides, proteins, and enzymes have not been characterized in varanid lizards, research on the toxicity of *V. griseus* may reveal salivary constituents which are effective in prey acquisition or in defense.

We thank David Blanchard for his case report and Fred Bohler, Andrew Snider, George Van Horn, and Tim Walsh for their assistance.

Submitted by **VICKIE BALLARD** and **FREDERICK B. ANTONIO**, Department of Herpetology, Central Florida Zoological Park, P.O. Box 470309, Lake Monroe, Florida 32747, USA; e-mail (FBA): fbantonio@hotmail.com.

SERPENTES

ARRHYTON EXIGUUM (Puerto Rican Garden Snake). **DIET**. The Puerto Rican garden snake is a small species that reaches ca. 45 cm in total length. It is terrestrial and has secretive habits. It is found under logs, rocks, tree stumps, and in termite nests. It actively forages during the day (Henderson and Crother 1989. *In* Woods [ed.], Biogeography of the West Indies: Past, Present, and Future, pp. 479–518. Sandhill Crane Press, Gainesville, Florida).

Here I report an observation of an individual *Arrhyton exiguum* feeding on an *Anolis* sp. egg at night. The egg (21 x 11 mm) was probably from the giant anole (*A. cuvieri*) based on its size. The observation occurred in a haystack hill located in the Sabana Seca area of Bayamón, Puerto Rico, on the northern karst belt of the island. Previous diet records include frogs (*Eleutherodactylus*), lizards (*Anolis*), worm-like lizards (*Amphisbaena*), and adults and eggs of blind snakes (*Typhlops*) (Rivero 1998. Los Anfibios y Reptiles de Puerto Rico. Editorial de la Universidad de Puerto Rico, San Juan, Puerto Rico. 510 pp.). This observation represents the first record for the island of a snake preying on an *Anolis* egg.

Submitted by **ALBERTO R. PUENTE-ROLÓN**, Box 1112, Ciales, Puerto Rico 00638-1112, USA; e-mail: culebron@atenas.com.

BOA CONSTRICTOR (Boa Constrictor). **DIET.** *Boa constrictor* is a widely distributed, large-bodied generalist, feeding on diverse types of prey items including mammals, birds, and lizards (Green 1983. *In* Janzen (ed.), Costa Rican Natural History, pp. 380–383. The University of Chicago Press, Chicago.), yet little is known of its life history. Boa constrictors have been documented to eat a wide variety of prey; however, only a few rodents have been listed, including "spiny rats," black rats (*Rattus rattus*), agoutis (*Dasyprocta*), and a juvenile tree porcupine (*Coendou rothschildi*) (Beebe 1946. Zoologica 31:11–52; Davis and Smith 1953.

Herpetologica 8:133–43; Mole and Urich 1894. Proc. Zool. Soc. London 1894:499–518; Tschambers 1949. Herpetologica 5:141). Here we report an additional rodent prey item, an adult big-eared climbing rat (*Ototylomys phyllotis*; Rodentia: Muridae). This rat plus an unidentifiable immature rat were obtained from an immature *B. constrictor* (84 cm SVL, 450 g without prey item) on 10 February 2000 at Parque Nacional Palo Verde, Guanacaste Province, in northwestern Costa Rica, at ca. 30 m elevation (10°21'N, 85°20'W). The snake was captured late in the afternoon near the intersection of the main road and the Cerro Calizos trail and placed in a cloth bag, where it regurgitated its stomach contents during the night. The snake was released at the point of capture after data were collected. Both prey items were well digested and identified from their teeth. The immature rodent was perhaps only a few days old and would have been dependent on its mother and possibly the offspring of the adult *O. phyllotis*. One of us (RMT) observed boas consuming additional prey items at Palo Verde, including a subadult opossum (*Didelphis virginiana*) (13 June 1982) and an adult male ctenosaur (*Ctenosaura similis*) (January 1991).

Ototylomys phyllotis is a common species of small, nocturnal rat that is found in a wide variety of habitats, often around rocks, caves, sink holes, or fallen trees. This species forages both on the ground and among vines and low vegetation, usually 3 m or less from the ground. Nests are found at ground level among rocks, under logs, or in low tree holes (Emmons 1990. Neotropical Rainforest Mammals: A Field Guide. The University of Chicago Press, Chicago. 281 pp.). This is the first record of predation by any species on *O. phyllotis*, and the first report of boas consuming *D. virginiana*.

We thank Andres Vaughan for capturing the snake, the Ministerio del Ambiente y Energia and Sistema Nacional de Areas de Conservación for providing us with the opportunity to work at Parque Nacional Palo Verde, and we especially thank Javier Guevara S. for facilitating our research permits. Deedra McClearn and the Organization for Tropical Studies provided outstanding logistic support for this project.

Submitted by **KRISTIN A. BAKKEGARD**, Department of Biological Sciences, Auburn University, Auburn, Alabama 36849, USA, and **ROBERT M. TIMM**, Natural History Museum and Department of Ecology and Evolutionary Biology, University of Kansas, Lawrence, Kansas 66045, USA.

CROTALUS WILLARDI AMABILIS (Del Nido Ridgenose Rattlesnake). **DIET**. We obtained fecal remains from a female *Crotalus willardi amabilis* (560 mm SVL, 151.6 g mass) collected 21 July 2000 in the Sierra del Nido, Chihuahua, México. The specimen was collected in a high elevation (2727 m) valley above Cañon del Alamo near a grassy meadow among sparse oak (*Quercus* spp.) and pine (*Pinus* spp.). Examination of these remains revealed dorsal guard hairs, claws, and the partial skull (with teeth) of the southern pocket gopher (*Thomomys umbrinus*).

The only published diet record for *C. w. amabilis* is of unidentified mammal hairs in the scat of wild-caught specimens (Armstrong and Murphy 1979. The Natural History of Mexican Rattlesnakes. Univ. Kansas Mus. Nat. Hist. Special Publ. 5:1–88). In their review of diet records for *C. willardi*, Holycross et al. (*in press. In* Schuett et al. [eds.], Biology of the Vipers. Biol. Sci. Press, Carmel, Indiana) cited only one record of pocket gopher consumption. In addition, Holycross et al. (*op. cit.*) did not discover remains of pocket gophers among 95 prey of *C. w. obscurus*, though nine of these records were identified only as "small mammals." However, Holycross et al. (*in press*. Southwest. Nat.) reported finding the remains of *T. u. emotus* in the stomach of a predated *C. w. obscurus*.

We thank Deron Hartman, Javier Banda, and Ray Queen for their assistance in the field.

Submitted by **ROBERT W. BRYSON, JR.**, Department of Biology, Sul Ross State University, Alpine, Texas 79832, USA (e-mail: rbry860@sulross.edu), and **ANDREW T. HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA (e-mail: holycow@asu.edu).

DIADOPHIS PUNCTATUS (Ringneck Snake). **ARBOREAL BEHAVIOR**. On 1 April 2000, I was looking for small arboreal crickets along St Hwy 38, N of jct. St Hwy 9 and St Hwy 38, Santa Clara Co., California, USA. While banging the end of my insect net against the branches of the trees along the highway in order to dislodge insects, I knocked a black-colored ringneck snake from a maul oak (*Quercus chrysolepis*). This snake is typically found on the ground under cover objects (bark, leaves, etc.) and is not known to have arboreal habits (Fitch 1975. Univ. Kansas Mus. Nat. Hist. Misc. Pub. 62:1–53). However, this individual (158 mm SVL, 189 mm total length) was on a branch ca. 1.5 m above the ground and at least 1 m away from the trunk. Once the snake hit the ground, it immediately coiled its tail in a distraction display and then crawled under my boot. The only other animals knocked out of the tree were 4–5 mm long ants, unlikely food items.

Submitted by **THOMAS A. STIDHAM**, Department of Integrative Biology, Museum of Paleontology, and Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA.

ELAPOMORPHUS QUINQUELINEATUS (Raddi's Lizard-eating Snake). **REPRODUCTION.** *Elapomorphus quinquelineatus* is a small, nocturnal, fossorial snake, that is occasionally found in leaf litter. It is distributed in forested areas of southeastern Brazil, from eastern Minas Gerais and Espirito Santo south to Rio Grande do Sul (Peters and Orejas-Miranda 1970. Catalogue of the Neotropical Squamata: Part I. Snakes. Bull. U.S. Natl. Mus. 297:1–347; Ferrarezzi 1993. Sistematica Filogenetica de *Elapomorphus*, *Phalotris* e *Apostolepis* (Serpentes: Colubridae: Xenodontinae). Dissertação de Mestrado, Depto. De Zoologia da Universidade de São Paulo. 199 pp.). It feeds on snakes, lizards, amphisbaenians, frogs, earthworms and insects.

On 9 November 1999, five specimens were collected in a pasture on the left bank of the Rio Itabapoana at the site of the new hydroeletric dam at Rosal, near Guaçuí, Espirito Santo, Brazil (20°55'S, 41°42'W). On 27 December 1999, a female (790 mm SVL, 880 mm total length) laid one egg and on 7 January 2000, she laid a second egg.

The eggs were whitish and elongate. They were incubated in a covered plastic box (15 x 11 x 6 cm), at ca. 24 ± 2°C, on moist soil. The first egg was lost to fungal infestation. The second egg

hatched after 74 days. The hatchling was a female (195 mm SVL, 220 mm total length, 4.30 g). It was kept in a glass box (30 x 20 x 14 cm) with soil, and a bowl of water. It remained buried most of the time; when on the surface it actively explored the environment. Earthworms and mealworms were offered but not accepted. It was force-fed weekly with snake tails but steadily lost weight and died at 43 days of age (215 mm SVL, 240 mm total length) having lost about 40% (1.8 g) of its birth weight. It went through two ecdyses. The specimen is now number 62471 in the Instituto Butantan collection.

We thank Paulo E. Vanzolini for his comments and review of the manuscript. This project was supported by Empresa de Eletricidade Vale Paranapanema.

HYPSIGLENA TORQUATA (Night Snake) and ***OXYBELIS AENEUS*** (Brown Vine Snake). **ENDOPARASITES.** To our knowledge, there are no reports of endoparasites for *Oxybelis aeneus*. There is a report of plerocercoids of tapeworms of the Order Proteocephalidea in *Hypsiglena torquata* (Diller and Wallace 1986. Southwest. Nat. 31:55–64). The purpose of this note is to report the presence of larval spiny-headed worms (Acanthocephala) in the body cavities of *H. torquata* and *O. aeneus*.

One hundred seventy-one *H. torquata* from Arizona (herpetology collections of Arizona State University [ASU], Natural History Museum of Los Angeles County [LACM], and University of Arizona [UAZ]), and 40 *O. aeneus* from Arizona and Mexico (LACM and UAZ) were examined for helminths. A mid-ventral incision was made in the body wall; organ surfaces and mesenteries in the posterior portion of the body cavity were visually examined for helminths. Oblong, whitish bodies, ca. 1 mm x 3 mm, were occasionally seen and these proved upon microscopic examination to be oligacanthorhynchid cystacanths. Infected *H. torquata* were from Maricopa County (ASU 2256, 2263, 2316) and Pima County, Arizona (UAZ 25003, 25027, 30619–30621, 31631, 42683, 47167). Infected *O. aeneus* were from Santa Cruz County, Arizona (UAZ 47314) and Puebla (UAZ 27050) and Sonora, México (UAZ 46662, 49265). Prevalence of infection (infected snakes/sample examined x 100) was 6% for *H. torquata* and 10% for *O. aeneus*. Specimens were deposited in the U.S. National Parasite Collection (USNPC), Beltsville, Maryland as: *H. torquata* USNPC 90584; *O. aeneus* USNPC 90585.

The presence of oligacanthorhynchid cystacanths in *O. aeneus* and *H. torquata* are new host records. Oligacanthorhynchid cystacanths have previously been reported in the colubrid snake, *Rhinocheilus lecontei* (Bolette 1997a. Southwest. Nat. 42:232–236; Goldberg et al. 1998. J. Helminthol. Soc. Washington 65:262–265) which is sympatric with *H. torquata* and *O. aeneus*. Oligacanthorhynchid cystacanths are also known from seven species of *Crotalus* from western North America (Bolette 1997a, *op. cit.;* Bolette 1997b. J. Parasitol. 83:751–752; Bolette 1998. J. Helminthol. Soc. Wash. 65:105–107; Goldberg and Bursey 1999. Herpetol. Rev. 30:44–45; Goldberg and Bursey 2000. Herpetol. Rev. 31:104) and the elapid snake, *Micruroides euryxanthus* (Goldberg and Bursey 2000. Herpetol. Rev. 31:105–106).

We thank Robert L. Bezy (Natural History Museum of Los Angeles County), Michael E. Douglas (Arizona State University), and Charles H. Lowe (University of Arizona) for permission to examine specimens.

LAMPROPELTIS TRIANGULUM TRIANGULUM (Eastern Milk Snake). **ANTIPREDATOR BEHAVIOR**. Many colubrid species use tail displays as antipredator mechanisms (Greene 1973. J. Herpetol. 7:143–161). *Lampropeltis triangulum* is one of the species that engages in some form of tail display, generally tail-rattling. Herein, I report the observation of a different form of display, pseudocephalism, in *L. t. triangulum* from Essex Co., Massachusetts, USA.

On 1 July 1998 at ca.1400 h, a gray-phase *L. t. triangulum* (660.4 mm SVL, 749.3 mm TL) was captured in an ornamental garden within a rural neighborhood. The weather was mostly sunny, and air temperature was ca. 24°C. During capture, this individual engaged in thrashing, tail-rattling in vegetation, and the release of musk. Once the individual's head was restrained, this activity ceased and the snake began to move its tail through the ground cover, as if undulating tail first. This "tail-leading" gave the appearance that the concealed body part moving through the substrate was the cranial portion of the snake. Occasionally, the tail stopped moving in this manner and was coiled into a tight ball and held aloft. This behavior closely resembles the behavioral pseudocephalism described in some snake species, notably *Micrurus fulvius* (Mount 1975. The Reptiles and Amphibians of Alabama, Auburn Printing, Auburn, Alabama, 347 pp.) and, to my knowledge, has not been reported in this genus. Defensive behavior such as this may be used to direct predatory strikes away from the cranial region. Diverting predatory strikes to the tail may be highly adaptive; the post-anal tail in snakes is anatomically and physiologically less vital than the cranium, and attacks directed to this area can be further deterred by defensive bites and the release of musk.

Two conspecific individuals captured in this area have exhibited a horn-like and a button-like termination to the tail (698.5 mm SVL, 822.8 mm TL and 685.8 mm SVL, 774.7 mm TL, respectively). In the former individual, this unusual tail tip retained a 10 mm segment of old shed skin. Such unusual tail morphologies may increase the efficacy of rattle displays (particularly when shed skin is retained) and may also allow for ease of movement during tail-leading or rattling behavior (Tiebout 1997 J. Herpetol. 31:290–292). This anecdote may demonstrate the plasticity in antipredator behavior of this species, and additional studies of such behavior may provide insight into the evolution of tail displays.

Florida Caribbean Science Center, 7920 NW 71st Street, Gainesville, Florida 32653, USA.

MICRURUS SURINAMENSIS SURINAMENSIS (NCN). **ABOREALITY**. At 2139 h on 11 January 2000, while walking a trail through secondary forest at the Madre Selva II Biological Research Station in Loreto, Peru (3°37.175'S, 72°14.873'W, GPS error = 13.5 m), we observed a *Micrurus surinamensis surinamensis* coiled on a vine which was wrapped around a vertical tree trunk ca.1.35 m above the ground. The snake had an SVL of 25.5 cm, a TL of 3.5 cm, and weighed 11.5 g. The surface temperature of the snake's resting site was 27°C. *Micrurus surinamensis surinamensis* inhabits lowland tropical forests in or near rivers in the Amazon. These snakes are known for their aquatic habits and primarily feed on fish and eels (Roze 1996. Coral Snakes of the Americas: Biology, Identification, and Venoms. Krieger Publ. Co., Malabar, Florida. 328 pp.). Arboreal behavior has been reported in three other species of *Micrurus*: *M. circinalis* (Sajdak 2000. Herpetol. Rev. 31:105), *M. fulvius* (Carr 1994. A Naturalist in Florida: A Celebration of Eden. Yale University Press, New Haven, Connecticut. 264 pp.), and *M. nigrocinctus* (Schmidt and Smith 1943. Publ. Field Mus. Nat. Hist., Zool. Ser. 12:129–134.).

Submitted by **RUSTON W. HARTDEGEN** and **BRIAN AUCONE**, Department of Herpetology, Dallas Zoo, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA; e-mail (RWW): ruston17@yahoo.com.

NERODIA SIPEDON SIPEDON (Northern Water Snake). **FORAGING**. A recent study suggests that juvenile *Nerodia sipedon sipedon* employ a "mixed foraging strategy," engaging in both active and sit-and-wait type predation (Balent and Andreadis 1998. J. Herpetol. 32:575–579). Here I present anecdotal evidence suggesting that adult *N. s. sipedon* may employ sit-and-wait foraging tactics, in addition to the active foraging tactics already documented (Ernst and Barbour 1989. The Snakes of Eastern North America. George Mason University Press, Fairfax, Virginia. 282 pp.).

On 13 July 2000 I observed an adult female *Nerodia s. sipedon* (571 mm SVL, 176 g) hunting bluegill (*Lepomis macrochirus*) in the shallows on the north shore of Barney's Lake, located on Beaver Island, Charlevoix Co., Michigan, USA. The area of the lake where the observation took place was exposed to the sun and was ca. 30 cm deep. The lake bottom was strewn with abundant sticks and tree branches.

When I began observing the snake, it was sitting motionless near a bluegill nest. Within a very short time three bluegills could be seen approaching the nest. When this occurred, the snake immediately began chasing the fish with mouth agape. The fish retreated and the snake quickly broke off the chase and returned to a spot near the nest where it again became motionless. This scene repeated itself three times over a period of ca. 10 min. At one point the snake briefly came up to breathe, and at another point it took up position under a large branch near the nest. At no time was the snake observed to be successful in capturing a fish.

Several studies have characterized *N. s. sipedon* as a generalist (Drummond 1983. Behavior 86:1–30; Meyer 1992. Foraging, Thermal and Spatial Ecology of the Northern Water Snake [*Nerodia s. sipedon*]. M.S. thesis. Central Michigan Univ., Mt. Pleasant. 64 pp.), which might favor a variety of foraging tactics if different prey have different habits (as suggested by Balent and Andreadis, *op. cit.*). It is unclear whether this observation represents an aberration, but it does seem clear that further work with adult *N. s. sipedon* in the field is warranted.

I thank J. C. Gillingham for comments on the manuscript.

Submitted by **KENNETH D. BOWEN**, Department of Biology, Brooks Hall, Central Michigan University, Mt. Pleasant, Michigan 48859, USA; e-mail: bowen1kd@cmich.edu.

PORTHIDIUM DUNNI (Dunn's Hognosed Pitviper). **DIET**. *Porthidium dunni* is endemic to Mexico where it inhabits the tropical dry forest of the Pacific Coast (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Cornell University Press, Ithaca, New York. 425 pp.). To date, nothing is known about its diet (Campbell and Lamar, *op. cit.*).

On 26 August 1999 an adult female (305 mm SVL, 40 mm tail length, 32.7 g) was collected at El Chorro Santiago Astata (15°52'31"W, 96°00'77"N), Oaxaca, Mexico, at an elevation of 140 m by Silvia Salas. The snake was humanely killed by freezing, fixed in 10% formalin, and preserved in 70% ethanol. It was dissected and its stomach contents were removed. Its stomach contained an adult *Sceloporus siniferus* (52.0 mm SVL, 115.0 tail length, 5.3 g). Both the snake (SS004) and lizard were deposited in the collection SERBO (Sociedad para el Estudio de los Recursos Bióticos de Oaxaca) de Huatulco, Oaxaca. This note provides new information on the natural history of *P. dunni*.

We thank Aurelio Ramírez-Bautista for his suggestions on the manuscript and for identification of the snake and lizard.

SIBON SARTORII SARTORII (Sartor's Snail Sucker). **PREDATION**. There is no documentation of predation by the domestic cat, *Felis catus*, on *Sibon sartorii*. On 23 August 2000 at 0920 h, ARH encountered a juvenile *F. catus* in a house ca. km 212 on the highway Pachuca-Tampico, Hidalgo, México, feeding on a juvenile *S. s. sartorii* . The cat had bitten off a 66 mm portion of the snake's tail when ARH attempted to rescue the snake. On 26 August 2000 at 0600 h, the cat caught and partially ate another juvenile *S. s. sartorii*. The uneatten portion of the snake was 117 mm in length and had several puncture wounds. The temperature on both days was <25°C. The only recorded predator of *S. s. sartorii* is *Micrurus* sp. (Kofron 1988. Amphib.-Rept. 9:145–168).

Submitted by **ALEJANDRA RAMIREZ HERNANDEZ** and **FERNANDO MENDOZA QUIJANO,** Instituto Tecnológico

Agropecuario de Hidalgo, km. 5.5 Carr. Huejutla - Chalahuiyapa, Apdo. Post. 94, Huejutla de Reyes, Hidalgo, 43000 México; e-mail (FMQ): mendozaq@mail.ibiologia.unam.mx.

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga). **ENDOPARASITES.** *Sistrurus catenatus* occurs from southern Ontario, Canada, diagonally through the central United States to Texas, New Mexico and extreme southeastern Arizona (Minton 1983. Cat. Amer. Amphib. Rept. 332.1–332.2). To our knowledge, there are no reports of endoparasites in this species. The purpose of this note is to report parasitism by the ascarid nematode *Hexametra boddaertii* and the presence in gut contents of larval physalopterid nematodes (*Physaloptera* sp.) and a cyst containing a larval spirocercid nematode (*Physocephalus* sp.) in *S. c. edwardsii*. The body cavities and guts of 57 *S. c. edwardsii* from the Museum of Southwestern Biology, Albuquerque, New Mexico, USA, were examined. A mid-ventral incision was made in the body wall; organ surfaces, mesenteries, and body cavity were inspected for helminths. Contents of the stomach and intestines were examined for helminths using a dissecting microscope. Stomach contents of MSB 54414 collected in Chaves County, New Mexico, USA (33°16'N, 103°58'W), May 1992 contained 2 third stage larvae of *Physaloptera* sp.; stomach contents of MSB 56580 collected in Chaves County, New Mexico, USA (33°16'N, 104°02'W), May 1993 contained 1 third stage larva of *Physaloptera* sp. and 1 cyst containg a larva of *Physocephalus* sp. Within the stomach musculature of MSB 56580 was found 1 female and 2 male *H. boddaertii*. Nematodes were deposited in the U.S. National Parasite Collection (USNPC), Beltsville, Maryland, USA: *Hexametra boddaertii* USNPC 89791, *Physaloptera* sp. USNPC 89792, *Physalopteroides* sp. USNPC 89793.

Sistrurus c. edwardsii represents a new host record for *H. boddaertii* and the second North American rattlesnake reported to harbor this nematode that was previously reported from *Crotalus cerastes* from California (Bursey et al. 1995. J. Helminthol. Soc. Wash. 62:78–80). New Mexico is a new locality record for *H. boddaertii*. Explanation of the larval nematodes found in the stomach contents is more problematic. Species of *Physaloptera* and *Physocephalus* utilize insects as intermediate hosts (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission, 2nd Edition, CABI Publishing, CAB International, Wallingford, Oxon, U.K. 650 pp.). Insectivorous lizards comprise over half of the prey items consumed by *S. c. edwardsii* (Holycross, unpublished data). Thus, we believe the larval nematodes found in this study are a byproduct of diet and do not represent parasites of *S. catenatus*.

We thank J. Tom Giermakowski and Charles W. Painter at the Museum of Southwestern Biology for specimen loans and assistance and the Wallace Research Foundation for funding.

Submitted by **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA, **CHARLES R. HOLYCROSS**, Department of Biology, Arizona State University, Tempe, Arizona 85287-1501, USA.

THAMNOPHIS ERRANS (Mexican Wandering Gartersnake). DIET. Members of this genus prey on a variety of vertebrates and invertebrates, including small mammals, amphibians, fish, lizards, slugs, earthworms, and leeches (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman, Oklahoma. 332 pp.). Little published data exist on the natural history of *Thamnophis errans* (*op. cit.*). The only prey item reported for this species is a shrew (Baker and Webb 1976. Herpetol. Rev. 7:112).

A small adult *T. errans* (ca. 400 mm TL) was collected in Cañon el Mesteño (2570 m elevation) in the Sierra del Nido mountains, Chihuahua, México on 23 July 2000. The specimen had a noticeable mid-body bulge and after palpation regurgitated a juvenile anguid lizard, *Barisia levicollis* (ca. 70 mm TL). This represents the second recorded prey item for *T. errans*.

We thank Deron Hartman, Javier Banda, and Ray Queen for their assistance in the field and Bob Webb for sharing his knowledge on this species.

Submitted by **ROBERT W. BRYSON, JR.**, Department of Biology, Sul Ross State University, Alpine, Texas 79832, USA, and **DAVID LAZCANO**, Laboratorio de Herpetología, Universidad Autónoma de Nuevo León, Apartado Postal – 513, San Nicolas de los Garza, Nuevo León, C.P. 66450, México.

THAMNOPHIS HAMMONDII (Two-striped Garter Snake). **PREY**. We documented foraging by *Thamnophis hammondii* around a seasonal pond (ca. 50 m L x 18 m W x 1 m D) located in Dulzura, San Diego Co., California, USA (32°37'N, 116°46'W) on property managed by the Bureau of Land Management. *T. hammondii* is often observed actively foraging in the pond or basking among the metavolcanic andesite outcroppings on the northern shore from as early as February to as late as October. Visual observations of *T. hammondii* at this study site were restricted to periods when the pond contained water, which is highly variable from year to year. The aquatic breeding amphibian community at this seasonal pond consists of *Spea hammondii*, *Bufo boreas*, *Hyla regilla*, and the non-native *Xenopus laevis* (ELE., pers. obs.; RNF and T. J. Case, unpubl.).

Reported herein as novel prey for *T. hammondii* are *S. hammondii* and the introduced species from South Africa, *X. laevis*. We also report *H. regilla* as prey of *T. hammondii* from this site. Documentation of prey items in all three cases was achieved by examination of stomach contents. On each occasion the snake was gently hand-palped until the stomach contents were disgorged. All snake weights reported were acquired subsequent to removal of stomach contents.

On 4 April 1998, a large female *T. hammondii* (308 g, 68.5 cm SVL) was observed crawling slowly in a serpentine fashion 20 m away from the perimeter of the stock tank. Upon hand capture and processing, one large adult *S. hammondii* (5.3 cm SUL) was recovered. One 35 mm slide print photo documented the snake and food item. It is noteworthy that *S. hammondii* has not previously been reported as a prey item for *T. hammondii* in spite of naturally co-occurring in many locations.

Little is known regarding predation on *X. laevis* in extralimital populations by native species. Crayon and Hothem (1998. Herpetol.

Rev. 29:165–166) reported predation on *X. laevis* by the black-crowned night heron (*Nycticorax nycticorax*) in Los Angeles Co., California, USA. Here, we report documentation of a native reptile using a non-native amphibian as a food resource. On 13 August 1998, a large female *T. hammondii* (163 g, 62.9 cm SVL) was hand captured while it was shore cruising in sparse emergent vegetation (*Eleocharis* sp.). One *X. laevis* (4.5 cm SUL) was recovered. The frog was deposited in the California Academy of Science (CAS 212359). On 22 October 1998, a juvenile *T. hammondii* (4.3 g, 20.5 cm SVL) was captured within 30 m from waters edge. One recently transformed *X. laevis* (2.6 cm SUL) was recovered (frog voucher CAS 212360).

Juvenile and adult *Thamnophis hammondii* are highly aquatic and primarily feed on fish eggs, fish, tadpoles, and small anurans (Fitch. 1940. Univ. California Publ. Zool. 44:1–50; Jennings and Hayes. 1994. Amphibian and Reptile Species of Special Concern in California. California Dept. Fish Game. 255 pp.). Additionally, because post-metamorphic *X. laevis* occupy a benthic environment, they are at great risk from predation by *T. hammondii* and only safe when large enough to exceed the gape of the snake. *T. hammondii* has been observed at the majority of aquatic habitats that support established populations of *X. laevis* in southern California (ELE, pers. obs.). The effectiveness of skin secretions from the non-native frog (*X. laevis*) as an anti-predator mechanism to deter predation from the native snake (*T. hammondii*) has not yet been examined or determined. From 1995 to present, we studied *T. hammondii* / *X. laevis* interactions in lentic and lotic habitats under various hydrologic regimes in southern California. Our data suggest that *T. hammondii* does not serve as an agent for controlling *X. laevis* populations. Consequently, it is unlikely to provide an effective barrier for the colonization and establishment of *X. laevis* in new aquatic habitats.

Larval and post-metamorphic *Hyla regilla* are often reported as a food item for *T. hammondii*. An additional record from this site is as follows; on 14 March 1996 a large female *T. hammondii* (163 g, 62.9 cm SVL) was captured and one gravid *H. regilla* (3.9 cm SUL) was recovered (frog voucher CAS 212361).

Special thanks to Joe Funk, BLM Ranger, for assisting with logistics, Ed Camp, for providing his knowledge of the local area, and Milan Mitrovich, Ron Pulido, Carlton Rochester, and Daniel Soper for assistance in the field.

Submitted by **EDWARD L. ERVIN** and **ROBERT N. FISHER**, U.S. Geological Survey, Department of Biology, San Diego State University, San Diego, California 92182-1015, USA.

THAMNOPHIS SCALARIS (Mexican Alpine Blotched Garter Snake). **DIET**. *Thamnophis scalaris* is an endemic Mexican species, occuring in the high-elevation conifer forest of the central Mexican Plateau (Smith 1942. Zoologica 27:97–123). Here, we report the stomach contents of eight *T. scalaris* collected between June and September, 1999, at the Area de Conservación e Investigación Ecológica El Bordo, Las Maravillas (99°41'W, 19°24'N), 17 km NW of Toluca City, México (elevation 2550 m). All snakes were measured, weighed, sexed and forced to regurgitate. Data are reported as mean ± SD. We obtained earthworms from seven *T. scalaris* (4M:3F, 328.7 ± 10.74 mm SVL, 38.5 ± 12.5 g, stomach contents 2.5 ± 0.8 g). One female (400 mm SVL, 42 g) consumed a deermouse (*Peromiscus maniculatus*, 10 g), ingesting the posterior legs first.

Very little is known about the biology of this species and this is the first report of wild *T. scalaris* feeding on earthworms or deermice. The only other stomach contents data for *T. scalaris* are two *Sceloporus* sp. (Fouquette and Rossman 1963. Herpetologica 19:185-201), and an adult anguid lizard, *Barisia imbricata* (Lemos-Espinal and Ballinger 1992. Herpetol. Rev. 23:117).

Submitted by **CRYSTIAN SADIEL VENEGAS-BARRERA** and **JAVIER MANJARREZ**, Laboratorio de Biología Evolutiva, Centro de Investigación en Recursos Bioticos, Facultad de Ciencias, Universidad Autónoma del Estado de México, Instituto Literario No. 100. CP 50000, Toluca, Estado de México, México (e-mail: sadiel@cibnor.mx).

THAMNOPHIS VALIDUS CELAENO (Mexican Pacific Lowlands Garter Snake). **MAXIMUM SIZE and REPRODUCTION**. *Thamnophis validus celaeno* is known only from the Cape Region of Baja California Sur, Mexico. The maximum size reported for *T. v. celaeno* is 730 mm SVL, with a tail length of 228+ mm (Conant 1969. Bull. Am. Mus. Nat. Hist.142:1–140). On 8 June 2000, AD and TAF collected a female *T. v. celaeno* at the Presa El Chorro, 2 km west of Agua Caliente, BCS, Mexico. Under Conant's (*op. cit.*) categorizations of color patterns, this snake was a "Group C" animal or, more generally, a member of the "Dark Populations." The animal was kept in captivity at the University of Colorado, Boulder, USA, and was measured on 20 July and 1 August 2000. These measurements averaged 777 mm SVL and 249 mm tail length. The snake gave birth to six live males, six live females, one dead female, and two partially developed embryos on 29 or 30 July 2000. The 13 offspring (including the dead female but not the partially developed embryos) averaged 155.1 mm SVL (SD = 8.5; range 135–165 mm) and 3.1 g (SD = 0.4; range 2.0–3.5 g). After parturition, the female had a mass of 169.4 g. This is the first record of a litter for *T. v. celaeno*.

The adult snake was collected and exported with permission from La Direccion General de Vida Silvestre (collecting permit FAUT-0030 and exportation authorization 11658). The adult female and offspring will be deposited in the University of Colorado Museum.

Submitted by **ALAN DE QUEIROZ**, **TARA A. FORBIS**, and **CHRISTY L. MANTANONA**, Department of Environmental, Population and Organismic Biology, University of Colorado, Boulder, Colorado 80309, USA; e-mail (AD): dequeiro@stripe.colorado.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ukans.edu/~ssar

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2001 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@slu.edu.

Future Annual Meetings

2002 — Crown Center Hotel, Kansas City, Missouri, USA. 3–8 July 2002 (with ASIH, HL)

About Our Cover: *Phyllomedusa camba*

The hylid frog genus *Phyllomedusa* ranges from Costa Rica to Argentina, and contains a number of large, colorful species, including *P. camba*, the Lowland Monkey Frog. Although only recently described as a "new" species (De la Riva 1999. Revista Española Herpetología 13:123–131), herpetologists have long known of this frog. Cannatella (1983. Proceedings of the Biological Society of Washington 96[1]:59–66) recognized that at least two species were represented within the geographically variable and widely distributed *P. boliviana*,and other workers have reported additional observations for this species under the names *P. boliviana* or *P.* sp.

This new species is relatively common and widespread. It occurs in the southwestern Amazon Basin, from southeastern Peru and western Brazil to eastern Bolivia, with a straightline distance of ca. 1200 km between endpoints. Although the ranges of *P. camba* and *P. boliviana* are mostly parapatric, examples of microsympatry are known in some parts of the Bolivian lowlands.

Phyllomedusa camba is an inhabitant of primary and secondary rainforests, spending much of its time above ground, both in low vegetation and in the canopy. Exclusively nocturnal, calling and breeding activity start with the first heavy rains and extend from November to March. Sexual dimorphism is evident with females reaching a snout–vent length of 84 mm, while males may reach 70 mm SVL. Eggs are deposited within folded leaves overhanging pools. Tadpoles are undescribed for this species.

The specimen on our cover was collected in May 1989 from rainforest habitat near Tarapoto, Peru, by Anthony Wisnieski for the National Aquarium in Baltimore, where it was photographed by **Will Brown**. This animal differs in some respects from other individuals of *P. camba*, notably in eye color, but is tentatively allocated to this species. Brown used a Nikon N70 with a 105mm macro lens and dual SB23 strobes, recording the image on Fuji Velvia film. After a brief period of working with wolves and big cats, Brown joined the staff of the National Aquarium as a herpetologist. Currently, he is affiliated with University of Virginia's Biology Department, where he conducts research on amphibian reproductive biology and genetics.

Separation and imaging of Brown's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

Joseph B. Slowinski (1962–2001)

Joseph Slowinski, Curator of Herpetology at the California Academy of Sciences, died on 12 September 2001 in Myanmar after being bitten by a Multi-Banded Krait (*Bungarus multicinctus*). A full obituary will be published in *Copeia* 2002(1). Meanwhile, a tribute to Joe appears at the following website: http://www.doctorbugs.com/Joseph_Slowinski.html.

SSAR BUSINESS

New Officers for SSAR

In recent years, the duties of Treasurer (an elected office) and Publications Secretary (an appointed office) have been handled together by Robert Aldridge (with the able assistance of his wife, Linda). Aldridge is "retiring" from these positions and the operations are once again being divided. SSAR is grateful to Bob and Linda Aldridge for their many years of outstanding service to the herpetological community.

Effective 1 October 2001, Breck Bartholomew took over as SSAR Publications Secretary. The new address for SSAR Publications is:

Breck Bartholomew
SSAR Publications Secretary
P.O. Box 58517, Salt Lake City, Utah 84158, USA
e-mail: ssar@herplit.com
Phone/fax: 801/453-0489

Effective 1 January 2002, the new Treasurer will be Theodora Pinou. Her contact information is:

Theodora Pinou
SSAR Treasurer
Department of Ecology & Evolutionary Biology
Osborn Memorial Labs, Yale University
165 Prospect Street, New Haven, Connecticut 06520-8106, USA
e-mail: theodora.pinou@yale.edu
tel. 203/432-5028; fax 203/432-5176

Previously, the Treasurer's Office handled membership transactions. In an effort to streamline this important societal function, a new membership office has been established. Matters concerning new memberships, renewals, or address changes should be communicated to:

Donald Schmitt
Director, SSAR Membership Office
P.O. Box 253, Marceline, Missouri 64658, USA
e-mail: ssar@memsys.com
tel./fax: 606/256-3252

Seibert Award Winners for 2001 Announced

The tenth annual Seibert Awards were presented at the 44th Annual Meeting of the SSAR in Indianapolis, 27–31 July 2001. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meetings. Awardees received a check for US $200 and a book from Academic Press. The winners:

Systematics: **Emily Moriarty**, Section of Integrative Biology, University of Texas at Austin, "Phylogenetic relationships of North American chorus frogs (*Pseudacris*)."

Physiology/Morphology: **Travis LaDuc**, Department of Integra-

tive Biology, University of Texas at Austin, "Effects of body size on the predatory strike of the western diamondback rattlesnake."

Ecology/Evolution: **Daniel Warner**, Department of Biology, Virginia Polytechnic and State University, "Phenotypes and survival of hatchling lizards."

Conservation: **John Marshall**, Department of Biology, Indiana-Purdue University, "Movements and macrohabitat selection in fen wetlands by the eastern massasauga rattlesnake."

The judges also acknowledged additional outstanding presentations as Honorable Mention recipients:

Systematics: **Si-Min Lin**, National Taiwan Normal University, "Molecular phylogeny and biogeography of the grass lizards, genus *Takydromus* (Reptilia: Lacertidae), of eastern Asia."

Ecology/Evolution: **Jason Kolbe**, Washington University, "Nest-site selection in natural and disturbed habitats: adaptive or an ecological trap?"

Ecology/Evolution: **Vanessa Quinn**, Indiana State University, "Male-male competition and female choice: consequences of the loss of a male signaling trait."

Conservation: **Kristie Gianopulos**, University of South Florida, "Response of the threatened sand skink (*Neoseps reynoldsi*) to controlled burning and clear-cutting in Florida scrub habitat."

The judges were Marion Preest, chair (The Claremont Colleges), Steve Adolph (Harvey Mudd College), Robin Andrews (Virginia Polytechnic and State University), David Chiszar (University of Colorado), Lisa Hazard (UCLA), Diana Hews (Indiana State University), Meredith Mahoney (AMNH), Kirsten Nicholson (Washington University), Ann Paterson (Williams Baptist College), and Chuck Peterson (Idaho State University).

SSAR Henri Seibert Award for 2002
